When a well is ready to be shot, the contractor notifies the oil company and the 'shooter'. When the latter arrives, the hole is measured to the sands with a steel tape. The measurement must be accurate within the half of a foot. The glycerine is then poured into the shells and each is lowered to the right distance. Each shell is conical at the lower end and concave at the upper, so that a series fits snugly together. While being lowered the shells are attached to a thick cord with a special releasing device. The last shell has on top a waterproof percussion cap, connected with a wire by which it can be set off with an electric spark. This is operated by a hand battery. It is the custom in the Illinois field, after the shot is set, to raise the casing considerably above the sand. This takes but an hour or two and eliminates any danger of collapsing or breaking the casing while in the hole.

When the explosion takes place, a person 100 yd. away will, after an interval of 30 to 40 seconds, feel a quick jar of the earth. This is followed by a muffled report which seems to come from any place other than below. After about a minute and a half a roar is heard from the direction of the well and gas can be seen pouring out, followed shortly by a column of oil and water. This begins to rise slowly and eventually reaches above the top of the derrick,

where it sprays out in the direction in which the wind is blowing. At the same time there is heard a rattling of pebbles and pieces of rock and slate against the derrick supports. For a moment or so dull thuds may be heard as rock fragments fall to the ground. The column of oil subsides in the course of several minutes until within a few feet of the top of the casing, where it pours out in a steady stream. If the well is a 'gusher' it will flow for several hours or until the drillers are able to cap it in. When the well has settled the drillers begin to re-set the casing and make preparation to clean the bottom preparatory to pumping.

There are two kinds of nitro-glycerine used in the field, the liquid and the solid. The latter is made into cylindrical forms and has the appearance of a yellowish transparent jelly. It has the consistence of rubber and can be readily handled without danger. There is some difference of opinion as to its efficiency compared with the liquid explosive. The Ohio Oil Co. has given it a thorough test and has found it wanting in explosive power. The advantage over the liquid is that it is easily transported and placed in a well. The E. I. Du Pont de Nemours Powder Co. is the most prominent one operating in the Illinois field, and its prices are considered the standard. These in 1909 were as follows:

| | |
|------------------------------------|---------|
| 10 quarts | \$25.00 |
| 20 quarts | 40.00 |
| 30 quarts | 47.50 |
| 40 quarts | 55.00 |
| 60 quarts and over, per quart..... | 1.15 |

Two cents per foot is charged for electric wiring. In case trouble is experienced in shooting and the shooter is detained, an extra charge of \$15 per day is made after the first day.

FREEZING METHOD FOR RESTRAINING MINE-WATERS.

Written for the MINING AND SCIENTIFIC PRESS
By EDWARD H. NUTTER.

A novel method for taking care of a large flow of water underground was devised and carried out at the Bessie mine on the third beach-line near Nome, during the past summer. It consisted of freezing off the end of the drift in which a stream of water had been struck when beginning work in the spring, and that had flooded the workings and drowned the mine. The idea occurred to John Brower, of Nome, to use refrigeration. He took a contract for doing the work. A line of holes was drilled down from the surface, and across the drift, with a Keystone drill. Pipes were let down these holes into the drift, and connected at the top with an ammonia machine. Sand was then shoveled into the drift through the holes, and freezing commenced. This was kept up until the latter part of August when the job was completed. A solid block of sand and ice was thus formed, connecting on all sides with unthawed ground, which completely dammed the drift and shut off the water from the rest of the mine. When this was done, the mine was unwatered and driving operations were resumed. The drilling and freezing required about a month and cost \$4000.

THE FOREST SERVICE AND MINING IN THE NATIONAL FORESTS.

By W. W. DYAR.

*From the inception of the policy of reserving certain of the public lands of the West for forestry purposes, it was realized that these lands must remain open to mineral exploration and development. The mining camps were largely situated in those elevated and timbered regions which would necessarily be devoted to forestry purposes. To withdraw these lands from the operation of the mining laws would be to take away the means of livelihood of a large part of the population, and to limit the production of those metals peculiarly essential to the prosperity of trade and commerce. Accordingly in the Act of June 4, 1897, Congress made an explicit declaration that the mineral lands within the Forest Reserves should remain open to mineral exploration and entry. This same Act provided for the creation of a field force, to protect, administer, and regulate the use of the Forest Reserves. When this force took active charge and began to make timber sales and issue grazing and other special use permits, it was soon confronted with many difficult and embarrassing questions in the mining regions. It found much of the land plastered over with unpatented mining locations, some in course of active development, others only occasionally worked, and many apparently abandoned. The proclamations creating the Reserves excepted therefrom 'all valid claims'. The land covered by invalid claims therefore became a part of the Forest Reserves. In order to know what lands were subject to the jurisdiction and control of the Forest officers it became important to find out what claims were valid and what invalid. Now, it happens to be the nature of mining claims not ordinarily to carry upon their face any unmistakable marks showing which are valid and which are invalid. It is not easy to separate the sheep from the goats.

The question of the validity of a mining claim under our law ultimately depends, of course, upon the question of a discovery of mineral within the meaning of the law. The difficulty of determining this question and the danger of attempting to pass upon it in the early stages of development was doubtless recognized by those then charged with the administration of the Forest Reserves; but, perhaps, the difficulty was not fully appreciated. At any rate a policy was entered upon of trying to distinguish the valid from the invalid claims, when application was made for patent and the land was about to pass definitely and for all time out of the power of the Government to control it for Forestry purposes. Then an examination was made by a Forest officer and a report rendered which laid the foundation for proceedings in the General Land Office to determine whether a discovery of mineral had been made and the requirements of the law complied with so as to entitle the claimant to a patent. A little later, when it became known that large bodies of apparently non-mineral lands within the Forest Reserves had

been located as mining claims and were held and used, not for mining, but to control timber, water-power sites, and other surface uses, a further step was taken. Investigations were made and, in co-operation with the Interior Department, proceedings were instituted to have such claims declared invalid prior to application for patent. Proceedings of this character, however, have generally been limited to cases of apparently glaring fraud, or cases in which the existence of the invalid claims worked some special injury to the Forest Reserves. The execution of the policy of examining and reporting on mining claims was for a time necessarily left to the local Forest officers—primarily to rangers, who it must be admitted, were not specially qualified for this particular work. No doubt they did the best they could. They manfully tackled the job; in some regions with great vigor, in others with more caution and discretion. The result on the whole was that this business quickly grew to proportions not originally contemplated. Once the machinery was set in motion it produced a grist of controversies irritating to the miners and prospectors and embarrassing to the Forest Service. It became evident that measures must be taken to limit the scope of these examinations and to have them made by men especially qualified for the work.

The spirit in which the Washington office was dealing with these questions is shown by the following quotation from a letter written on January 16 of the present year to one of the District Foresters: "It is our feeling here that the Forest Service must steer a judicious middle course. On the one hand, Forest officers must not permit an excess of zeal to make them seem hostile to bona fide claimants. On the other hand, they must not be over cautious in dealing with claimants who are not entitled to their claims. Sometimes we shall lose cases because of methods of practice or interpretation of the law by the Land Office which cause us to fail to establish a point rightly taken. We have got to work, of course, for the establishment of right principles, whether we lose or not. Yet we must face the fact that when we lose many cases there is not much for us to do but say we were wrong. We cannot explain the situation on the ground that somebody else was wrong." Since that letter was written we have lost many cases—a good many cases. Like the writer of that letter, however, I am not disposed to quarrel with the decisions of the Land Office in these cases. The Registers and Receivers it is true are appointive and not elective officers. They, like other judges, may sometimes mistake the law or misinterpret the facts. But they are residents of the locality in which the controversies arise. They are in touch with the local needs and local sentiment, and their views and decisions form a wholesome corrective to that tendency toward bureaucratic methods inseparable from the conduct of the great Department at Washington.

A few days after the letter just referred to was written, and in answer to a letter and memorandum from one of the District Foresters discussing the mining conditions, the Washington office had this to say: "The memorandum appears to argue that the mining law should be strictly enforced regardless of the character of the land, but in your summary it is

*Abstract of address delivered before the American Mining Congress at Goldfield, Nevada.

recommended that a more liberal policy be adopted in regard to contesting claims on the ground of insufficient discovery when the good faith of the claimant is apparent, and there is no doubt but that the land is being taken solely for its mining values. It appears to me that we can safely go a little farther than this and not contest mining claims the patenting of which would not in any way jeopardize the interests of the National Forests. It would appear that * * * we need only concern ourselves to the extent of contesting claims which we believe are being taken for purposes other than mining, and the patenting of which would interfere with the interests of the National Forests." So you can see that the Forest Service was not at that time, as many persons seem to believe, trying to invent new methods of interfering with mining and of preventing the patenting of mining claims; but on the contrary was seeking to limit its activities so as to disturb the mining interests as little as seemed possible, consistent with the great purposes of conserving the forests, and protecting the watersheds.

In the meantime the Forestry Committee of the American Mining Congress had taken up with the Forester this and other questions affecting the mining interests. The result of the interviews, resolutions, and correspondence between them has been recited in the report of that committee. The rule, which the Forester agreed with the committee to adopt, read as follows: "Mining claims in any National Forest apparently held in good faith for mining purposes will not be further examined unless the passage thereof to patent would be prejudicial to the Government if the said claims should in fact be found to be invalid. If any such claim is apparently not held in good faith for mining purposes, it will be examined by a qualified mining expert to ascertain the true conditions, and the report of such mining expert will be submitted to the Department of the Interior for its consideration." This rule was accordingly promulgated, but with a further modification by which the words "prejudicial to the interests of the Government" were changed to "prejudicial to the interests of the National Forests." In other words, the Forest Service very properly concluded that any interests of the Government other than those of the National Forests should be left to the Interior Department.

Since the adoption of this rule we have been trying to get it into speedy operation in the field. We have had some difficulty in making some of the field officers realize its full meaning. And, unfortunately, we have on hand a heritage of cases coming from the earlier times when the policy had not been clearly defined. The Service fully realizes that many of these cases were originated by it on insufficient grounds, without sufficient knowledge of the facts, and in some cases where it believes its attitude was right, it cannot produce sufficient evidence to sustain its position. From all such cases we are now retiring as fast as possible; and in making that retreat we are not taking particular pains to preserve our dignity. To hold on firmly to the things that are right, it is good to let go quickly of the things found to be wrong. You perceive that I am not averse to

making admissions. But I was not a member of the Forest Service at the time most of these things were done; and as you doubtless know, it is comparatively easy to acknowledge the mistakes of other people.

About the middle of June last, in a further attempt to adjust the relations of the Forest Service and the mining interests on a more satisfactory basis, I was directed by the Forester to visit, as far as seemed necessary, the mining camps situated in various National Forests, investigate the conditions, find out what we were doing that was wrong, or that worked injustice to the miners, and to suggest remedies if possible. In the performance of the task entrusted to me I visited most of the mining camps and mining centres of Colorado; some of those in Utah, California, Oregon, Idaho, and Montana, stopping finally in the Black Hills of South Dakota. I talked with prospectors, mine owners, mining engineers, mineral surveyors, mining lawyers, and, of course, with some Forest officers. I tried, to the best of my ability, to get at the actual facts. I was, and am, a firm believer in the general policy of forest conservation, but I had not been identified with the Forest Service long enough to become wedded to any particular measures of administration. In the course of this investigation I met with some surprises and formed some pretty definite conclusions, and in the interest of a better understanding I am going to tell you frankly what some of them were. "In the first place, I did not find a single miner who had ever been prevented from prospecting freely on the National Forests, or who knew of anybody else who had. I did find in the towns somewhat removed from the mining regions, persons who seemed to believe that prospecting had often been stopped and that the Forest Service didn't want it to be free. And only four days ago I met on the train the editor of a mining paper, who, I believe, honestly thought that this was true. In the second place, I found that in some localities, and at various times in most localities, the Forest Service had, as it seemed to me, made a fundamental mistake in the matter of examining mining claims when patent is applied for. With the best of intentions, no doubt, some Forest officers seem to have assumed that the validity of all mining claims was fairly open to question and that all alike must be examined impartially to determine whether there had been a discovery of mineral and whether the requisite amount of development work had been done. The principle involved had not seemed quite so clear when the protests and complaints came up separately to the Washington office, but on the ground and in contact with actual conditions it became clear to me that the course pursued ignored a fundamental principle that always ought to be observed by a government in dealing with its citizens: namely, that until some fact or circumstance appears tending to show the contrary, it should always be presumed that the acts of all citizens are done in good faith with intent to observe the law. As one group of miners put it to me, "The Forest Service assumes that we are all timber thieves and calls upon us to prove that we are honest miners and law-abiding citizens." Now, I am glad to say that never was the general attitude of the Service as a whole. It is not

now the attitude I am sure of any part of it, or in any locality. It may be that recent instructions have not yet been fully brought home to every Forest officer, but they soon will be. Every effort will be made to limit the examinations for discovery to cases in which there is some reason to think that the claimant is using the mining laws illegitimately to get title to timber lands, to ground controlling a water-power, or some other surface right or advantage tending to defeat those purposes for which the National Forests were established. Examinations of claims above timber line, or on barren ground, where no such surface rights can possibly be obtained, should, of course, never be made.

In the third place, I became convinced that, largely because of the mistaken attitude just mentioned, partly because of occasional arbitrary acts of individual officers, partly because of petty annoyance arising from a too strict construction of regulations by other officers, mining had in fact been hampered to some extent and in some localities; and to a greater extent had been discouraged by the false impressions thereby created as to the general purposes of the Forest Service. Measures have been taken, and still others will be taken, to remove these causes of trouble. In spite of all that has been said, the Forest Service realizes that the development of mines is just as important a policy as the conservation of timber and the protection of the watersheds. The two things must go hand in hand; and a plan must be perfected by which mining and forestry can be carried on in the same territory with the least possible friction and the greatest mutual helpfulness. We are not in love with this business of examining mining claims. It is not a weapon of precision. When we train it on the mob pillaging the store we are in danger of hitting a law-abiding citizen working quietly in the neighboring shop. But it is the only weapon we have as the law now stands; and let no one infer from anything I have said that we will hesitate to use it whenever we have grounds to suspect that the mining laws are being wrongfully used to get timber lands out of the National Forests, or to acquire title to lands controlling a water-power, and by that means, subject to a private monopoly that which both nature and the policy of the Government have devoted to the general good. There will be no going backward in these respects.

I said a few minutes ago that the practice of forestry and the development of the mines on the public domain were equally important to the country at large. I want to add that they are deemed equally important by the laws of the United States now in force. But there is no use shutting our eyes to the fact that they do interfere to some extent with each other, and that to some extent each must give way to the other. If a mining claim located in the midst of a valuable body of timber does in fact show a valid discovery of mineral and full compliance with the mining law in other respects, then the Forest Service should not and cannot legally make any objection to the issuance of a patent. But the issuance of that patent does in fact take away some of the lands of the National Forests which are valuable for forestry purposes. On the other hand, I think it just

as clearly the law that by the creation of National Forests the miner has lost the right to go upon the public mineral lands included therein, and freely take timber for mining purposes. This right he formerly had under the Act of Congress of June 3, 1878, but when the lands were withdrawn and made a part of a National Forest he lost that right. And to that extent mining has had to give way to forestry.

Now I am perfectly aware that the report of the Committee of Forestry here today takes an opposite view. The Committee says that it is unable to find any Act of Congress repealing the law of 1878. There is none. Neither is there any Act repealing the Homestead Laws, the Timber and Stone Act, or the Desert Land Act. Yet nobody contends that these statutes are still in force within the National Forests. The truth is that the same thing happened to the Act of 1878 as happened to the laws last mentioned. None of them were repealed, but they all ceased to operate upon the National Forest lands as soon as the lands were reserved, because their continued operation upon those lands would have defeated the very purposes for which Congress authorized the reservations to be made. I want to call your attention to the fact that this law of 1878 is not a part of the mining laws. It is not distinctively a mining law at all. Mining is only one of several purposes mentioned in it. The material parts of it read as follows: "All citizens of the United States and other bona fide residents" of certain States and Territories named in the Act "shall be, and are hereby, authorized and permitted to fell and remove for building, agriculture, mining, or other domestic purposes, any timber or other trees growing or being on the public land, said lands being mineral," etc.

Your Committee itself says this is a bad law and is liable to abuse. The Committee pledges itself to support a movement to repeal this law and get a better one enacted. Whether this law is a bad law or not as applied to unreserved public lands, Congress knew it was a bad law as applied to lands especially devoted to the growth and perpetuation of timber. It knew that its operation, whether abused or not, would devastate the Forest Reserves, and defeat the purposes of their creation. Therefore when Congress, by the Act of March 3, 1891, authorized the President to set aside and reserve lands for forestry purposes, and by the Act of June 4, 1897, authorized the Secretary of the Interior to make "such rules and regulations and establish such service as will insure the objects of such reservations, namely, to regulate their occupancy and use, and to preserve the forests thereon from destruction," Congress did by that legislation sweep away from the lands so reserved this Act of 1878, along with the Homestead Act, the Timber and Stone Act, and any other existing law which would result in destroying the forests. The Forester is simply enforcing the law as he believes it to be and is advised by his law officer that it is.

With the law of 1878 out of the way, what are the rights of the miner as to using timber? He, of course, cannot go outside of his claims to get timber from the public land. If he owns a single unpatented claim there is no question but that he can cut the

timber therefrom to use on the claim, or in connection with its development. But how is it in the case of a group of unpatented claims? I believe there is no case in which this question has been directly decided by the courts. The Secretary of Agriculture and the Forester, acting under legal advice, hold that the right of the owner of a group of unpatented claims is to cut the timber from one claim of that group and use it on another claim of the group, or entirely outside the group, if its use in that place tends to develop the claim from which it is taken. If it does not tend to develop that claim when it is used outside the claim, then he cannot take it for that purpose, and in that case his only right is to take timber from the claim for use on the same claim. In other words, we think the miner's right to take timber from a group of claims is controlled by practically the same principle as that of doing assessment work upon the claims of a group; and that is, as I understand it, that assessment work done on one claim may apply on another claim if such work tends to develop the latter claim, otherwise not. Now, I am not going to make a legal argument to sustain this position; I will only say in a general way, that we believe this to be the law because of those decisions which hold that the right acquired by the location of a mining claim is the right to possess and use it for the purpose of developing a mine on that claim, and for that purpose only. To illustrate this position, I will cite you now to only one decision: that is, *Teller v. United States*, 113 Fed. Rep. 273, decided by the Circuit Court of Appeals of the Eighth Circuit, December 30, 1901. You will there find reference to other authorities bearing upon this question. Now it is possible, of course, that we may be mistaken in this position; but we do believe it to be the law, and in enforcing it we believe we are obeying the law. If there are differences of opinion as to this, the obvious and proper thing to do is to get a case into court and have this question of law finally settled.

There has been a great deal of criticism of the Forest Service in various quarters and from various motives. I suppose there will be more. I have done a little of it myself. I am willing to admit that it is something of an anomaly in American affairs to have a great number of executive agents controlling a great territory and vested with authority in relation to certain subjects, to say to the inhabitants thereof, "You may do this and you may not do that." But in the opinion of the great body of the American people and in the opinion of their representatives in Congress already enacted into law, the end justifies the means. The preservation of forests and the protection of watersheds has come to be a matter of vital necessity to the common good. Some such scheme of control is the only practicable way of accomplishing that purpose. The legal and constitutional foundation for it is unassailable. The United States is the owner of these lands. It may do with them what any other owner of lands may do. But I would not rest this authority on any such narrow and technical grounds. These National Forests spread over the boundaries of various States. They protect the ultimate source of rivers which traverse two-thirds of

the area of the United States, and discharge their waters into two oceans. One of these rivers at least forms an international boundary. This, therefore, is a National, not a State or local affair, and the National Government has undoubted jurisdiction on broad as well as narrow grounds.

It has been said, and doubtless will be repeated, that the Government, through the Forest Service as now conducted, holds these lands and derives a revenue from them on the principle of a great baronial landed estate. This is a perversion of the facts. The United States spends in protecting and administering these lands vastly more than the revenue it derives from them. It only insists that those who make a special use and derive a special benefit from the lands so protected shall pay something for the privilege and thereby share part of the expense. The superior equity of the Western people in these Western lands which they have redeemed from savagery is recognized by turning over to the States in which the various National Forests are situated one-fourth the gross income derived from such forests to be expended on county roads and for county schools. So far as it can, consistent with the ultimate ends of forestry, the Government grants free use of timber to the prospector, the small miner, and the ranchman. By this system of free-use permits it endeavors to so provide that no man shall fail to make a home or erect necessary buildings and fences, or fail to develop a mine for want of timber needed in the early and critical stages of development.

The sudden introduction of this system of control, of conservation, of issuing permits, in place of the old free and unrestricted use, was undoubtedly a shock to many of the Western people. It could not have been otherwise. It upset the habits, the customs, the preconceptions of generations of prospectors and frontiersmen. On the part of the Forest Service mistakes were made, some injustice was done, some arbitrary and indefensible acts were committed. It was inevitable that such should be the case. When new policies are rapidly put into operation over a vast territory, through numerous agents who must necessarily grope their way to an understanding of the situation and its requirements, nothing else can be expected. But with time, with patience, by constant effort to ascertain the true conditions, and adjust regulations and administration to them; with the help and co-operation, and even the protests of the people affected, and of such bodies as the one I am now addressing, I believe that matters will be so worked out that the great and beneficial purposes of the Forestry policy will be accomplished satisfactorily to all parties. I believe they will be accomplished without subjecting any American citizen to a degrading or humiliating official control in his daily life and business affairs; without interfering with any personal or property rights; without infringing upon any of the reserved powers of the States; and without violating any of those fundamental principles which underlie our scheme of Government, and which, it should never be forgotten, are of more vital importance to the American people than the conservation of any merely material resources possibly can be.

DISSEMINATED CHALCOCITE DEPOSITS AT RAY, ARIZONA.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. TOLMAN, JR.

The brilliantly stained hills in the vicinity of Ray, the stains and occasional stringers of carbonates of copper, and the sheets of native copper found in irregular veins, early attracted the attention of prospectors. Even back in the Apache days there was considerable prospecting, mining, and some shipment of native copper. Finally the best developed, and what was then considered the most promising, of the claims of this area, came into the possession of the enterprising firm of L. Zeckendorf & Co., of Tucson, Arizona, and in 1899 these were sold to English capitalists, who organized the Ray Copper Mines, Ltd. This company carried on development for about two years, building a narrow-gauge road from the mines to Kelvin, where they put up a small concentrating plant, and pushed underground work on the Ray and Tribune group of claims. Unauthentic reports put high estimates upon the total amount of money spent by the company, but I have been informed by one who was connected with the company that over a half million dollars was spent in bona fide development of the properties.

Neither this company nor those who preceded had an adequate conception of the extent of the orebody, and did not understand the character of the deposit. Development was confined to veins, veinlets, and stringers, and so this attempt spelt another failure. Ray had no railroad connection at that time. All material was hauled about 50 miles from Red Rock, on the main line of the Southern Pacific railroad. Fuel was scarce, wood costing \$10 per cord. The small mill of about 300 tons capacity did not effect a good recovery, nor could such a plant be expected to pay under these conditions. The stringers of native copper were rich but irregular, but the workings that passed through the oxidized zone everywhere ran into a sulphide-specked schist of such low grade that no thought of the possibility of this rock becoming pay-ore occurred to the miners; nor could it have been treated with profit under the conditions then prevailing. Finally, after the Bingham and Ely mines became demonstrated successes, certain Salt Lake mining men told Philip Wiseman that they would like to test other disseminated deposits. He explained that this was exactly what the Ray was, and he returned to attack the property as a great low-grade body.

Ray is situated in Pinal county, not far from the Gila county line, on Mineral creek, five miles north of Kelvin. The latter is on the Phoenix & Eastern railroad, and at the union of Mineral creek with the Gila river.

The geology of the Globe quadrangle, a few miles to the north, has been studied by F. L. Ransome. No Government examination of the Ray district has as yet been made. William H. Truesdell* described in this journal the formations at Ray, following Mr. Ransome closely. He suggests that the diabase is

the source of the ore. J. E. Spurr has just finished a detailed study of the Ray properties, but his results are not available, as they are presented to the company in a private report. It is to be hoped that the company will see fit to allow the publication of the scientific results of this examination. I have had the pleasure of recently making a geological reconnaissance of a few days duration in the vicinity of Ray, and the accompanying geological map, Fig. 1, presents some of the results of this investigation. It is, however, only a sketch made for the purpose of giving a graphic notion of the relation of the formations, and not their actual boundaries.

The Pinal schist is the oldest and the basal formation of the region. It appears as a block the greatest elongation of which is in a northwest direction. This schist is identical in all respects to that found in the Miami-Inspiration area, except that in the south-

Fig. 1. Sketch Map of the Geology Near Ray, Arizona.

eastern portion of the block, near the great fault, it has suffered greater silicification than appears at Miami. The Pinal schist has wide distribution in southern Arizona, but has not been much in favor with the prospector as an ore-bearing formation. It appears in most of the desert ranges southwest of Tucson. It is probably the upper member of a tremendous series of stratified pre-Cambrian gneisses which outcrop in the Catalina and Rincon mountains 60 miles to the south, and reach great development in the mountains of northern Sonora. To the west of the Ray schist-block is a diorite that is provisionally put in the pre-Cambrian. The Paleozoic rocks appear on the east, separated from the schist by an important fault. This series appears to be quite similar to the Globe formations named by Mr. Ransome 'the Apache quartzite' and 'the Globe limestone'. The impression given by distant views is that the Ray Paleozoic rocks attain greater development than those of the Globe quadrangle. They are not involved in the great chalcocite mineralization, and will not be considered further.

The first post-Paleozoic intrusion is a diabase appearing as sills and dikes. An examination of the

*MINING AND SCIENTIFIC PRESS, June 5, 1909.

drill-logs shows that an extensive sheet, or two sheets in places, underlies a considerable area of the low-land adjacent to Mineral creek, extending up to the Mineral creek fault described later. As the surface outcrops of the diabase are not prominent, no attempt is made to give expression to this formation in the map and sections, except the few dikes which I examined. The granite porphyry and porphyritic granite intrudes the schist, the quartzite, and the diabase (Fig. 2), and is therefore later than all of these. It resembles the Schultze granite of Mr. Ransome, which, in my judgment, was the source of the mineralization of the Old Dominion and the Miami-Inspiration deposits, but of course it is not permissible to apply that local name until the two granites are proved to be a part of one and the same intrusion. I shall therefore call this the Ray granite. Where the main mass splits into dikes, it grades into a fine-grained porphyry. It occurs as isolated knobs, entirely unconnected at the surface. The schist has been floated up on the billowy surface of this granite, the under surface forming a warped trough, and erosion has proceeded just far enough to expose a few of the upper projecting points of the granite.

Fig. 2. Cross-Section at Ray.

All the later overlying formations may be considered as a non-mineral bearing mantle subsequent to the primary mineralization, and therefore of little importance to the economic geologist in this particular case. Mr. Ransome has named the lower detrital conglomerate 'the White Tail conglomerate', and the overlying tuffs and lavas, 'the dacite', and the upper conglomerate 'the Gila conglomerate'. Had Mr. Ransome been acquainted with the great complex series of igneous and aqueous-igneous flows, of detrital conglomerates, and of lake-beds, of which the above formations are but the outer fringe, he would probably not have separated the White Tail formation from the Gila formation, and have put each in a separate geological period, because separated by a lava-flow.

Faults.—The Mineral creek fault separates the dacite and the Paleozoic rocks from the schist. It is by far the most important structural break of the region, is of great displacement, and cannot escape the notice of even the casual visitor. The schist-block has suffered intense fracturing, but the fractures have been subsequent to silicification. These silicified breccia-zones may have been lines of fault-movement, but the contorted schist does not furnish datum planes by which the dislocation may be determined. In one case such movement was proved by finding a diabase dike cut off along one of the breccia zones.

The ore stratum.—Interest centres upon the orebody, or ore-stratum, as it may be called. This develops at 100 to 250 ft. below the surface, and has an average thickness of 100 ft. under the silicified por-

tion of the schist. In the vicinity of the Sharkey area to the northwest the schist is soft, decomposed, bleached white in places, and again brilliantly colored by iron compounds. Erosion has produced amphitheatre effects in the softer spots, but nowhere on the surface is there copper. It has all gone below. It is in this neighborhood that the great bonanzas have been found, the glass model of the orebody showing how the ore-zone swells upward and downward, to thicknesses in places of 350 ft., and with copper content higher than elsewhere. The section (Fig. 3) across a portion of the west orebody, furnished by the courtesy of the Ray Consolidated Co., will give a graphic notion of the deposit as an ore-stratum or underlying ore-blanket. Recent development in the bottom, and along the banks of Mineral creek, show that the stratum extends up to the Mineral creek fault, and that the ore here is partly oxidized throughout nearly its entire thickness, cuprite and chalcocite occurring together in the diabase, which is well developed in this area.

The log of one drill-hole affords an interesting example of the processes of secondary sulphide enrichment. The 'oxidized zone' shows silicates and carbonates of copper, but the assay returns give only a trace of the metal. Then suddenly large quantities are found at the top of the secondary sulphide zone, and then the amount decreases with lessening chalcocite, until finally the pyritized schist falls below 1½% copper and ceases to be commercial ore. The lower boundary of the orebody is an artificial plane corresponding to the points where the copper falls below the economic minimum. The mineralization, however, continues to undetermined depths, the chalcocitization decreasing until finally the schist contains only primary pyrite.

The copper conglomerate.—There is an interesting occurrence of copper conglomerate in Copper canyon. The stream conglomerate at the bottom of the arroyo is cemented with carbonates and silicates of copper. Several attempts have been made to treat this in leaching plants. The deposit was formed by the seepage of a small amount of copper-bearing water out of the precipitous sides of the canyon, causing a precipitation in the gravels of the dry-wash, of copper minerals, mainly by evaporation.

Sampling the orebody.—Prospecting for and sampling of the ore has been carried on extensively by churn-drilling. The holes are placed on co-ordinates, 200 ft. being the distance between each hole. In case any hole is considerably above or below the average in copper content or shows a marked change in thickness of ore, auxiliary holes may be drilled in the neighborhood. Churn-drilling is employed exclusively, the Star machine seeming to be in favor with both drillers and management. Samples were taken at first all the way down the hole, but now no sample is preserved until the chalcocite appears. A string of three samples, however, is kept in tubs, and with each new bailing the oldest sample is discarded. As soon as the chalcocite is detected, the two preceding samples are taken. The sludge of each bailing is run through a split-box, designed by Ralph C. Nowland, the resident engineer in charge of the sampling, one-eighth of the sludge running into the sample pail, and the sample is dried and sacked.

The rate and cost of drilling is shown from the following given me by one of the drillers. One machine running from October to June drilled 14 holes, 11 of which were cased. Ten shifts were lost during this time, but frequent shut-downs of short intervals were necessitated by shortage of water; average distance per shift $15\frac{1}{2}$ ft.; average distance drilled during straight-work 25 to 30 ft. Mr. Stenger, the general superintendent of the Ray Consolidated Copper Co., states that the cost of drilling up to date has varied from \$2.25 to \$3.50 per foot.

Any statement of the ore proved will be out of date, for drilling operations are constantly adding new reserves to those already demonstrated, and as far as I am aware the outer boundary of the ore has not yet been discovered by the drilling operations of the Ray Consolidated. I believe that the Mineral creek fault is the boundary on the east, and the only boundary that can be assigned to the ore-zone as yet with any confidence. In the thicker portions of the orebody every drill-hole means the addi-

Fig. 3. Cross Section Through West Orebody.

tion of more than a million tons of ore. During March, April, and May the ore-development averaged 4,000,000 tons per month for 11 drills, and two drills have since been added. The report of the executive committee on May 22, 1909, in regard to the mineral ground not yet developed reads, "of the 1000 acres of mining claims owned, about 500 acres display the same character of rock and surface indications as the areas in which development has been and now is being carried on, and a greater part of this acreage promises the development of commercial ore deposits." The recent statement copied in this journal, to the effect that the Ray Consolidated Copper Co. has 50,000,000 tons of $2\frac{3}{4}\%$ ore developed, and attributed to D. C. Jackling, the general manager, was probably the attempt of some one not officially connected with the company, to revise former estimates and to keep them abreast of recent development. Mr. Jackling on October 2 wrote as follows in regard to this estimate: "I have been misquoted if it has been said that we have fifty million tons of ore of a grade of $2\frac{3}{4}\%$ developed at Ray. We have at the present time fully developed, by drilling and underground checking, approximately thirty-seven million tons of ore of a grade of 2.3%. The area fully developed is approximately one hundred acres. There is, of course, a very large quantity of ore that is partly developed and indicated by drilling, but while these incomplete developments give assurance that we will develop many more million tons of ore than the amounts above stated, and in all probability much more than is already developed, the positively and fully de-

veloped ore at the present time does not exceed the above stated figure."

The Gila Copper Co., owning neighboring land, claims to have about one-half as much mineral-bearing ground as the Ray Consolidated; formal development, however, has been only recently started, and is now being pushed in connection with the work of the larger company. No authoritative estimate of the tonnage of the Ray Central Co. is known to me. Their holdings, while not as extensive as the Ray Consolidated and the Gila, overlie the centre of the ore-stratum, and when worked will add materially to the product from this great orebody. The Hercules & Arizona owns some of the richest ground along the Mineral creek fault.

The thickness of the capping will necessitate caving operations, and the high assay value of the ore, compared with other deposits of anything like the same size, will probably more than offset the higher cost shown by caving methods in the past over steam-shovel mining. I am sanguine as to the results that will be accomplished when proper caving methods for such an orebody as the Ray are perfected. It is not impossible that caving operations on a large scale will show even lower costs than the average for steam-shovel work.

CARE OF THE GAS ENGINE.

By L. H. SNYDER.

*A gas engine should give good satisfaction if carefully looked after. Do not put it in a place where the rain will beat on it or the first thaw will drench it with water. The weather may turn cold and there will be a hard freeze, to say nothing about the dirty mess and the rusty parts. Always make it a point to see that the oil cups are turned off and filled, when you shut down, then they are always ready for use. It soon will become a habit to do this and to open them in starting. I prefer an engine which has grease cups rather than oil, because the grease will be used as needed, and there is not the danger of going away and leaving the lubricators open, which means so much oil wasted, fire-risk increased, and the cups run dry. The cooling water should be adjusted so that the discharge is at a temperature of about 200°F . for the highest efficiency, and in the winter, as an extra precaution, I would advise drawing all of the water out of the tanks as an insurance against a cracked cylinder. Alcohol may be used as an anti-freezing solution, but I would go to the extra trouble of drawing out the water, even if alcohol is used, as it will evaporate in time.

Failure of a gas engine to start is usually due to one of the following causes: First, there is no gasoline in the fuel-tank; second, no spark, weak batteries, loose or broken connections; third, excessive back-pressure or clogged exhaust; fourth, the firing apparatus not working properly; fifth, in winter, when the fuel-tank is outside, and it should always be there as a precaution against fire, it may be found that the gasoline is too cold to vaporize and it will be necessary to warm the carburetor by wrapping hot cloths around it (never use an open flame); sixth, the mixture may be either too strong or too weak.

*Abstract from *Gas Review*.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Idle Mining Claims.

The Editor:

Sir—Referring to the article of Mr. Edmund B. Kirby in your issue of October 2, I agree with Mr. Kirby in the general idea of the article and in nearly every particular. But why does he not add that such a law as he proposes is exactly what Mexico has today. An example in actual successful operation will do more to remove that natural timidity of the general public in regard to changing the law than any amount of argument. This law has been long in operation; it answers the purpose of encouraging the development of the mineral resources of the country; it is satisfactory to all parties concerned: the American investor finds no cause to complain of trouble over his titles; in fact he has less trouble over titles in Mexico than in his native land. It may not be patriotic to say so, but the truth is that, for developing the resources of the country, the laws of Mexico are far better than our own. They accomplish the very object which Mr. Kirby so earnestly aims at. Parties with a large 'acreage' receive a perceptible jolt at every recurrence of tax assessment returns with the result that they begin to drop off from their outer holdings what they do not really need. Property thus abandoned reverts to the general Government and is at once open to any one who desires to take it instead of passing into the hands of the tax-title shark where it is still further removed from any chance of early development.

VICTOR G. HILLS.

Denver, Colorado, October 21.

Carbons for Diamond Drilling.

The Editor:

Sir—In the issue of the MINING AND SCIENTIFIC PRESS of August 21 appears an article by John M. Fox, entitled 'Diamond Drilling at Tonopah'. In this article reference is made to what is called 'doctoring' carbon, and Mr. Fox apparently bases his remarks upon conditions of affairs which existed more than ten years ago. In the first place, the sale of carbons, or black diamonds as the stones are better known, is confined to not more than six separate companies which are all well known, and would not dare to practise the unscrupulous methods mentioned by Mr. Fox. These companies, with the exception of one which has its own source of supplies in Brazil, buy their carbons unbroken from European dealers and they, themselves, split or break the carbons after they have reached this side. Competition in this business is so keen, and the field is confined to so few companies, that such dishonesty or deception would soon ruin the company indulging in such practice.

Mr. Fox, however, has ground for asserting that stones have been colored, but this occurred, as the writer has hinted in the foregoing statement, a num-

ber of years ago. The erroneous opinion that all good carbons were black caused users to fight shy of carbons which were of a reddish tinge or gray, although these stones were as well adapted to drilling purposes as the black stones. This avoidance of the so-called 'off color' stones became a source of concern to one of the dealers as he found himself carrying a stock of carbon gray or red in appearance, altogether too large for his comfort. Knowing that these stones were first-class and equal to any on the market he had little hesitation in coloring them so as to make them marketable. This practice he continued for some time until the prevailing erroneous opinion regarding the proper color of diamonds for drilling was wiped out. This came about gradually, and at the present time and for several years past no attempt has been made to deceive the purchaser by coloring the carbons. Owing to the limited number of companies engaged in the sale of black diamonds, and because of the harm that might be done them because of Mr. Fox's statements, I hope that you will see fit to print this letter.

Economic Conditions in Colombia.

The Editor:

Sir—I have read, with much interest, the second article regarding Colombia, by F. Lynwood Garrison, April 17, regarding malaria. I thoroughly agree with the theory that the malady is conveyed by mosquitoes. I have a vague idea I read in a pamphlet of the Liverpool Tropical School of Medicine, that the 'Culex' mosquito, the yellow fever variety, possessed a very short proboscis, and the 'Anopheles' an extremely long one. Also I believe it was stated the male proboscis in the latter class was longer than that of the female. It was also stated that the male alone conveyed infection, but that for every male there were more than a hundred females. Now, I contend that sheer 'funk' is the cause of malaria to a great extent, or at least its evil effects; if a man pauses to see, after 'swatting' a 'stika' if the proboscis is short or long, the best thing he can do is to clear out of the country, for it is very probable he will go under. In the jungles of North Queensland, Australia, the Anopheles is plenteous, and malaria, dengue fever, and even beri-beri, and various other malignant fevers are rampant, but few deaths result. In a year probably not more than a score die from these causes, excepting, of course, at Townsville where the 'new chum' congregates.

The prospectors, miners, and timber-gatherers, all whites living there, take no notice of the mosquitoes except to abuse them, nets are few and far between, and quinine scarcer than whiskey. On the other hand, in West Africa, where the white man is pampered, and he has his clinical thermometer, and drug-case, and stock of scarce literature, it is no wonder the deaths are many. Let a man live clean, avoid the frying-pan and greasy foods, take warm baths and wear white and light clothing, clean, and with frequent changes, take a little whiskey and quinine, the both strictly in moderation and work, not molly-coddle himself, keep dry feet by being well shod, and

he need not fear malaria and kindred ills. I put in three years in the jungles of West Africa, and five in the fever country of North Queensland, and one year in New Guinea, the most fever ridden spots on earth, and in the whole time never lost a day with fever. It is well to remember many hold the idea that the excessive use of quinine is cause of the dreaded 'black-water' fever. Also remember that simple malaria without complications has never been known to cause death, and that 'cowards die many times before their death'.

A Russian Money Trust.

The Editor:

Sir—The article entitled 'A Russian Money Trust', in your issue of August 7, by George E. Walsh, appears to treat in a rather general way a subject upon which much accurate information is available. He says "Half a dozen mine owners control the platinum-producing districts of the Urals around the mining settlement of Miac," etc. I presume the settlement referred to is Miassky Zavod on the line of the Trans-Siberian railway. This will be news to the fortunate gentlemen referred to, and perhaps Mr. Walsh will be good enough to give you their names, so that you can mail copies of the issue to them, with his regards. The statement that Russia used this "absolute monopoly" "to help her recuperate" after the close of the Japanese war is certainly an astounding piece of information. Since 1898, when I first visited the Iss platinum fields, I have been under the impression that the bulk of the Ural platinum claims are held by a French company. This company has also a long contract with the Shuvalof Estate, its principal competitor, for the purchase of all the latter's raw platinum at a fixed price per pood. These two producers operate in the Iss, some 300 miles north of Miassky Zavod. A smaller producer of low-grade platinum is Demidof, at Tagil, 50 miles south of Verkotur.

Last winter in St. Petersburg I had the pleasure of a consultation with a gentleman who is the manager of Mr. Polyakof's platinum property, on the river Lozva, some 500 miles north of Miassky Zavod (Miac?). A Putilof dredge worked profitably on this mine during 1908, and the platinum was disposed of entirely independently of the French Iss company. To my knowledge there are at least 100 independent peasant operators on the river Tura, and platinum dust passes current among them for purchase of tobacco, tea, etc. As these people are for the most part working illegally on other owners' ground, it does not seem that any very close watch is kept.

For \$2.50 Mr. Walsh or any citizen of the United States may obtain a permit to locate and patent platinum-bearing ground in the north Ural, produce platinum, and sell it where he pleases. I have been the possessor of such a permit for ten years, and it is good for life. Large areas of the north Ural in the platinum belt remains unprospected; free Government lands open to location. Some new deposits will probably be found. At present it is true that a practical monopoly of the platinum business, regulated from Paris, exists. To break it up seems hardly the

legitimate function of the United States Geological Survey, but would be a quite conceivable object for a private company. That all the platinum ground in Russia is now in the hands of one company, or group of producers, is, however, very far from the truth.

Mr. Walsh should remember that railway trains go far nowadays, and it might pay him to buy a ticket to the station of Goroblagodat on the Perm railway, in order to more closely investigate the platinum situation. As I expect shortly to be coming back to London by way of the Trans-Siberian, I will look out of the window at Miassky Zavod, to see what is going on. The train goes through rather early in the morning, but possibly I may see one of the Miac syndicate out shoveling, if he happens to be working on the night shift.

Nikolaievsk, East Siberia, September 15.

Colloids and Adsorption.

The Editor:

Sir—In your issue of September 25, 1909, page 425, appears a paragraph on adsorption in which this sentence is found: "Adsorption is especially characteristic of the peculiar substances known as colloids which form the bulk of clays and on which their plasticity is believed to depend."

It is true that the mineral grains of most clays are coated by a film of colloidal matter, and in some cases this colloidal matter may constitute the bulk of the clay, as in some impure surface clays, but the colloids play a smaller part in the composition of most clays, it being claimed that in many of the common clays there is but a small proportion of the total ingredients which are capable of assuming the colloidal state by the action of water alone (Iowa Geological Survey, 14, p. 90, 1904). In the case of many kaolins, the purest of all clays, there is some doubt as to the existence of colloids. Schlossing found that there were what he determined to be colloidal substances in koalin, and found them to be singly refracting, but Kasai, on the other hand, disputed this, since he determined the apparently colloidal material to be doubly refracting.

Regarding the plasticity of clays and its causes, the colloidal theory (see Ashley, Transactions American Ceramic Society, 1909, p. 530) is probably the most widely accepted today, but this does not in any way conflict with the affirmation that the colloids are present in but small amount. Grout found (West Virginia Geological Survey, 3, 1906) that using a dilute solution of agar-agar, 0.08%, increased the plasticity of certain clays from 36 to 60%. The colloidal theory does not seem to have received much attention in this country. Many writers hold to the molecular attraction theory. Ladd (Georgia Geological Survey Bull. 6A, p. 39, 1908) advocates the theory that the mutual attraction between water and clay particles and surface tension between the water films determines the plasticity to a large degree. Purdy believes that plasticity is due to adsorbed salts, or to salts otherwise held, that on addition of water form a viscous solution about the grains.

E. K. SOPER.

Ithaca, New York, October 7.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Tailing is the property of the patented land on which it lies. It makes no difference as to its origin, nor how it came there. The only way in which such tailing may be acquired is by purchase. Tailing on land open to location becomes the property of the locator of such land.

Nitrogen of the air amounts to about four billion tons. On the basis of the present annual consumption, allowing no replacement, the air contains enough nitrogen to provide fourteen thousand million years' supply of saltpeter. The world's demand increases by about 100,000 tons per annum.

Mule-back haulage is not an anachronism. The deeply carved escarpment of the western Sierra Madre in Mexico forbids the construction of permanent wagon-roads, and railways will be few for many decades. Meanwhile the mineral development of that region is proceeding at such a pace that a greater demand for the services of the *arriero* and his *atajo* will exist ten years from now than has ever been witnessed in the past.

Clay may be defined as a mixture of minerals, chiefly silicates of aluminum, iron, the alkalis, and the alkaline earths. Predominant among these is kaolin ($\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2 \cdot 2\text{H}_2\text{O}$). Some feldspar is usually present. Upon most of these residual un-kaolinized grains is a film of colloid. The colloid material may be partly organic, and also consist of colloidal iron, manganese, and aluminum hydroxides, and colloidal hydrated silicic acid. The plasticity is now generally considered to depend upon the amount of colloid present, though other causes are urged.

A **catalytic agent** is a substance which promotes a chemical change, or interaction between two substances, without itself suffering any permanent change. The change may be of a positive, accelerating, or of a negative, retarding, character. Water vapor in small traces promotes the chemical action of oxygen with many of the elements, which show no tendency to unite with carefully dried oxygen, even when they are strongly heated. In fact, water is to be regarded as one of the commonest catalytic agents. Only a few cases of retardation of chemical activity by catalytic agents are known.

Asphalt is a general term which denotes the various forms of bitumen or mineral pitch found in nature or produced by refining processes. An essential property of asphalt so defined is that it melts at temperatures near that of boiling water; this property makes it available for use in various industries. Natural asphalt is not known in the United States in sufficient quantity to warrant exploitation at present, though it is widely distributed in California. Certain crude petroleum in California, Texas, Kansas, and Oklahoma contain considerable quantities of asphalt in solution, the proportion rising to more than 35% in some oils. Gilsonite, grahamite, and other hard bitumens are found in several of the

Western States, notably Utah and Oklahoma. Bituminous rock, including all kinds of rock that contain an appreciable quantity of asphalt or bitumen intermingled with the rock particles, occurs in California, Utah, Oklahoma, Texas, Kentucky, and Wyoming.

Pitch-blende occurs in fissure-veins, in igneous rocks, such as granite. It is valued for its uranium and radium content. It is not found in sedimentary rocks like sandstone, although alteration products of it may be found therein. Such alteration products are colored yellow or greenish, and, when in sufficient concentration and quantity, are valuable for their uranium content. The radium value in these is small, as a rule. It is found in vein matter in stringers varying from knife-blade thickness to several inches. It is 'bunchy'. The associated minerals in addition to vein matter are sulphides such as zinc blende, galena, and iron pyrite. The latter usually predominates.

Monazite is essentially an anhydrous phosphate of the rare-earth metals, cerium, lanthanum, and didymium ($\text{Ca, La, Di} \text{PO}_4$). There is nearly always present a varying but small percentage of thorium, ThO_2 , and silicic acid, SiO_2 , which are very probably united in the form of a thorium silicate, ThSiO_4 . Some monazites contain but a fraction of percentage of thorium, while others have been recorded that showed the presence of from 18 to 32%; but the majority contain from 3 to 9% of this oxide. It is the presence of the thorium oxide that gives the monazite its commercial value. The analysis occasionally shows also the presence of other constituents, as the yttrium and erbium oxides, zirconia, alumina, magnesia, lime, iron oxides, manganese oxide, and titanium oxide.

Polymorphism is a phenomenon shown by many minerals. Some substances are known to occur in more than one kind of crystalline form, that is, with different crystallographic molecular arrangements. For example, monoclinic and orthorhombic sulphur; the different forms of TiO_2 , rutile, anatase, brookite. Compounds occurring in such a manner are said to be polymorphic. They yield identical liquids, solutions, and vapors, and must have identical chemical molecules. Whether there is any other molecular difference between polymorphic forms of one compound than the crystallographic arrangement of the molecules is not always determinable. In some cases the change from one polymorphic phase to another may be accompanied by molecular polymerization. In general, polymerization, or the existence of different multiples of the simplest molecules in different phases of a substance, is indicated upon the transition, or inversion, of a substance from one phase to another by the liberation, or absorption, of a large amount of heat. Whether there is polymerization in the pyrogenetic compounds upon crystallization from molten liquids is a debated question. According to Doelter some of the pyrogenetic silicate minerals yield much heat upon crystallization, indicating polymerization upon crystallization. But Vogt concludes from his study of slags that there is little or no polymerization of the silicates formed in them.

Special Correspondence.

LONDON.

Mexico Mine of El Oro.—Tomboy.—Caucasus Copper.—Yuspenssky Copper.—Development Policy.

Details are now to hand relating to the Mexico mine of El Oro, situated immediately to the north of the Esperanza, which in turn is to the north of the El Oro. The report of the company for the year ended June 30 shows an increase in the efficiency of the plant and a decrease in costs. During the year under review 101,105 tons of ore were crushed and treated by cyanide, yielding \$905,062 gold, and \$352,496 silver, a total of \$1,257,559. The extraction was 94% of the gold and 87 of the silver. In addition, 500 tons of rich sulphide, containing metal worth \$112,294, was sold to the smelter, and gave a net return of \$91,706. The total mining costs, including development, were \$573,450, or at the rate of \$5.67 per ton, which compares favorably with the figures for the previous year, which were \$6.33. The ore reserves on June 30 were 191,655 tons, assaying \$10.90 in gold and 7 oz. of silver. The most interesting discovery during development was in the seventh, or bottom level, where a vein of sulphide ore was struck 500 ft. from the shaft, 15 ft. wide, and assaying 2½ oz. gold and 20 oz. silver. This orebody is part of a northern extension of the west vein in the adjoining Esperanza. The total receipts during the year from the sale of bullion and ore, interest, and other sources, were £280,815, and the costs at the mine and in London were £125,649, leaving a gross profit of £155,166. Out of this, dividends amounting to £112,500 have been paid, £25,000 written off cost of plant, and £8300 provided for income tax. The company was formed at the end of 1904, and commenced to pay dividends just a year ago, when £45,000 was distributed. The paid up capital of the company is only £180,000, and the dividends already distributed amount to £157,500.

Another property under the control of the Exploration Co. is the Tomboy Gold Mines, Ltd. This company operates the Argentine mine, at Telluride, Colorado. The report for the year ended June 30 shows that the content of the ore continues to decrease, a fact which has a decided effect on profits. Two years ago the profit was £155,310, and a year ago £87,115, whereas for the last fiscal year the profits were only £59,861. The amount of ore milled was 102,844 tons, which yielded \$487,486 by amalgamation, and \$332,970 by the sale of copper and zinc concentrate. Other small items, amounting to \$12,112, brought the total receipts to \$832,569. A year ago the figures were: 104,091 tons of ore, \$657,561 from the plates and \$341,459 from the sale of concentrate. The amount of ore reserves on June 30 was 400,000 tons, which is practically identical with the amount a year ago. The working costs have been reduced during the year to \$4.67 per ton, as compared with \$5.13 a year ago. The year commenced with a balance in hand of £66,331, which, added to the profit, made a disposable balance of £125,594. Out of this sum, £60,000 has been paid as dividend.

Nowadays, when low-grade copper ores are proving payable, there seems to be a chance for the unfortunate Caucasus Copper Co., which has been for the last nine years trying to make a success of the low-grade but extensive copper deposits at Dzansul, Caucasus, Russia. The capital has been provided by a number of substantial mercantile houses at London, and members of the firm of J. S. Morgan & Co., the English branch of J. P. Morgan & Co., have, perhaps, the largest holding. The concentration and smelting problems have been extremely difficult. Some of the best talent in England and America has been requisitioned in vain. At first it was thought possible to smelt the ore without concentration, and large sums of money were spent in the attempt. After that, efforts were made to concentrate magnetically with equally unsatisfactory results. More recently, by the advice of one of the directors, James Colquhoun, late manager for the Arizona Copper Co., another effort has been made to concentrate on tables. The ore is friable, and a large proportion of slime is formed, so that the recovery is low. The exact figures of extraction are

not given, but a sentence in Mr. Colquhoun's report gives some indication of the situation: "Counting on no more than a 50% extraction, which, of course, will be exceeded, the property can be brought into a highly profitable condition." Tables to treat 250 tons per day are already at work, and additional tables now under construction will shortly increase the amount treated to 500 tons per day. Close study is being made of methods of dealing with the tailing and slime. After many initial difficulties, the reverberatory furnace began to run successfully in September, and the output is now about 110 tons of copper per month. Mr. Colquhoun has had charge of operations since April. According to the report for the year ended May 31 just issued, it is seen that the indebtedness of the company has been increased by £293,100 during the year. Of this amount £191,540 has been spent on new plant and in acquiring additional copper properties adjoining, while of the remainder, £66,690 represents the loss on the working account. The liabilities of the company amount to £1,511,727, of which £500,000 is in ordinary shares, £503,100 debentures, £452,900 in loans, and other creditors £55,727.

Another Russian copper mine that has had a rough time is the Yuspenssky, in the Akmolinsk district, of Siberia, owned by the Spassky Mine, Ltd., a company which also owns the smelter at Spassky, and the Karagandy coal mine. This property is very different from that belonging to the Caucasus company, for it contains an unusually rich ore. At the hanging wall the ore is practically pure chalcocite, then comes bornite also nearly pure; afterward a silicious gangue gradually reduces the copper content. There is no actual foot-wall, and the question to settle is the economic limit in each cross-cut. When the company was first floated the market boomed it wildly, and the shares went to a high premium. Certainly the nature of the ore deposit justified to a certain extent the enthusiasm of shareholders, who also had the advantage of reliable reports by Pellew-Harvey & Fell, and by E. T. McCarthy. There have been many difficulties in the way of successful operation, such as want of transportation conveniences, unsympathetic labor, and terrible weather in the winter, but bad management has also much to answer for. Last year the directors made a general sweep of the staff in Siberia, and appointed H. C. Woolmer, general manager, F. C. Knight, smelter manager, R. M. Percy, superintendent at the Karagandy coal mine, and C. Farmer, manager at the Yuspenssky mine. It was found that far too much permanent work had been done at the surface at all three points, and it became necessary to dismiss many of the workmen. Development on a large scale was stopped at Karagandy, and extra efforts were made to get the company's railway between the coal mine and smelter into such efficient order that plentiful supplies could be stored at each point, and thus make it unnecessary to operate the railway during the winter season. One of the great hinderances to successful operation hitherto has been the constant exhaustion of supplies. For instance, there might be plenty of fuel at the smelter, but the supply of ore ran short. During the year ended September 30, 1908, the amount of copper produced was 1322 tons, which realized £102,697. Of this amount 430 tons were produced during the first six months, and 892 during the second half. Mr. McCarthy states that the re-organization is progressing satisfactorily, and that costs are being cut down in many directions. For the present the production of copper will not be greater than 200 tons per month, and only one furnace will be in use. Early next year another furnace will be blown-in, and the output will be accordingly increased. Mr. McCarthy has lectured the shareholders for their continued demands for figures relating to ore reserves. He gave them some information about the nature of the deposit and the method of mining that is advisable, explaining that this was a case where the craze for 'ore reserves' and the development of the mine years ahead of the smelter-capacity would only embarrass the engineers. With a hanging wall of this kind, which always requires careful watching, there is reason for restricting development.

The Selukwe gold mine, in Rhodesia, has fallen on evil days, and the directors are doubtful as to the best policy to adopt. The mine is situated 120 miles northeast of

Bulawayo, and operations commenced in 1898. The company was floated by the Bechuanaland Exploration Co. The capital is £321,000, and the only dividends have been three at 10% each, distributed in August, 1902, and February and August, 1903. Some of the shares were issued at a substantial premium. For the last few years losses have been made, and the report for the 12 months now issued shows a further loss. Forty stamps crushed 61,392 tons and yielded on the plates 11,799 fine oz. The cyanide plant treated 41,618 tons and produced 3050 fine oz. Together with 31 oz. recovered in concentrate, the total yield was 14,881 oz., which sold for £63,357. It will be seen that the yield by amalgamation was 3.84 dwt., and by cyaniding 1.46 dwt. per ton. The costs of mining, milling, and cyaniding were £62,969, but in addition to this the costs are increased by £13,223 for development and repairs, and £17,004 for depreciation. The debit balance for the year's work, without taking into consideration any London expenditure, is £29,000. During the previous year the loss was £13,000, and the year before that £28,647. The financial position of the company is therefore serious. The outlook at the mine is far from encouraging. As the developments did not disclose any payable ore the directors acquired adjoining claims containing the Nigger Reef, but

large returns and just entering upon a career of production, the best of the Cobalt properties, with large surplus and astonishing dividends, are almost wholly neglected for the porphyry coppers. These admittedly require five years of time and large expenditures to bring them to production, and may or may not be profitable, depending largely upon the engineers and metallurgists in charge. The public pays apparently little, if any, attention to dividends, mine values, financial condition, or mine or financial management, so long as a market quotation allows the counting of paper profits.

Rumors of possible apex trouble between the Tuolumne and the North Butte, based upon the filing by the latter company of an unimportant quit-claim deed, were made the ground of an attack upon the shares by a large short interest, aided in turn by active bear traders. The stock broke from \$4.25 to \$2.93 and rallied the moment holders realized they had taken fright at a shadow. The shares recovered more than one point in a half day's trading. The news of a very important strike in the Lucky Tiger, near Moctezuma, Mexico, created no little interest in local mining circles. A telegram states that the Sooy vein has been opened up on the seventh level exposing an orebody assaying 120 oz. silver and \$4 gold. The property was examined

recently by a prominent firm of engineers acting for English interests, and appearances at the time were such that the option held was allowed to lapse. Now the owners, who are mostly capitalists of Kansas City, Missouri, are congratulating themselves that the deal did not go through.

It is anticipated that the next statement of the Copper Producers' Association will show a sufficient decrease in stocks on hand to impart a materially better tone to the market. Just at present the market is quiet, with prices ruling somewhat lower, electrolytic at 12¾ to 13, with lake grades at 13 to 13¼. The talk of a copper combination which has been heard for the past two months seems to have been hushed for the present, though the fact that the Phelps-Dodge company is now the largest individual holder of Greene-Cananea, and the further fact that during the past few days there has been some exceedingly heavy buying of Butte Coalition,

said to be for account of the Amalgamated would seem to show that these important factors in any such organization are at least working into close relations. Butte was quite a heavy buyer of Davis-Daly in the Eastern market.

BRITISH COLUMBIA.

Rossland Items.—Phoenix Output Increasing.—Vermillion Forks Coal.—Telkwa District.

The Le Roi 2, Ltd., the only company paying steady dividends in Rossland district, has declared another of two shillings per share. This is the third payment of like amount this year. The bond which Charles Dempster, of Rossland and New York, has been working under on the Hattie Brown property in the South Belt has been permitted to lapse. One of the principal payments fell due a few days ago and while the bondholders were willing to go ahead with development, they did not feel warranted in making any big payments on the principal sum. Contracts have been let for the haulage of ore and concentrate from the Velvet mine to the railway siding near Frontier, a distance of seven or eight miles. Two four-horse teams will be able to handle the output of the mine for some little time to come. The actual hauling of ore has not begun as yet, but things are being put into shape as fast as it is possible to do so.

With seven big furnaces working full blast at the Grand

Part of British Columbia.

this is proving to be equally unsatisfactory. The amount of ore exposed is about 60,000 tons, but only a quarter of this is payable. The engineer's estimate is that 15,291 tons in a vein 30 in. wide, averaging 8.63 dwt., are payable, while 102,113 tons are also developed, but will not pay for extraction. Under these unfavorable circumstances the directors have requisitioned further expert advice, and have postponed the shareholders' meeting until such has been received.

NEW YORK.

Ely Stocks.—Lucky Tiger.—Copper Combination.

In the New York mining market the continued advance in shares of the companies operating at Ely, Nevada, has been unquestionably the feature. Ely Central continued its leadership, backed by a spectacular advertising campaign and vigorous support, in the face of occasional large profit-taking selling orders. Ely Consolidated, McDonald Ely, Ely Witch, Ely Northern, and some other stocks of the Ely camp, have also been active. Some arbitrage business has been done between New York and Salt Lake. Indeed the Mormon capital seems to be the Western centre of activity in the shares. While traders have welcomed anything in the way of a real market movement, some of the more conservative have commented upon the apparent perversity of the public. Properties like Goldfield Consolidated, yielding

Forks smelter and increased activity at the Greenwood smelter, demanding a heavy tonnage of ore for treatment, the output of the Boundary mines for the week ending October 23 exceeded all prior records and went up to 43,569 tons. The Granby company shipped nearly 9000 tons more than for the first week in October, and surpassed the former high record for this year of February 13 by 2000 tons, sending out 27,573. Next week it is likely the eighth furnace will be put to work. The shipments from the Mother Lode mine last week were the heaviest that have been sent from the mine so far this year; namely, 11,396 tons. Shipments from the Oro Denoro were above the average for this property, 950 tons going to Greenwood. The average shipment was sent out from the Snowshoe to Trail smelter, amounting to 3650 tons of ore. Since the Dominion Copper Co. closed down last year there has been owing to the miners about \$22,000. The New Dominion Copper Co. did not feel obliged to liquidate this debt, but the desire to avoid friction caused the company to propose to pay on the basis of 75c. on the dollar. The local merchants have agreed to discount all accounts related to this matter 12½%. The miners have accepted the combined offer. A crusher will be removed from Boundary Falls to the Rawhide mine in a few days. Work may be got under way there the early part of this month.

The Vermillion Forks M. & D. Co. will shortly get out two cars of coal for the Hedley Mining Co. for test purposes. This coal can be shipped into Hedley from Princeton and sold at about half the cost for fuel from the Crows Nest and other districts. The Vermillion Forks company expects to find a ready market for part of its product in Spokane, Washington.

For some time speculation has been rife as to the value of the coal and copper deposits of the Telkwa district of northern British Columbia. The coal deposits have now been examined carefully by a prominent Pittsburg coal expert whose report is considered favorable. The coal appears to be of a good quality for coking or steam purposes and in places is found in large quantities. It is expected that the Grand Trunk railway will build a branch line to tap the district. It is said that one big syndicate has located 72 miles of Telkwa coal land. The Extension mines, Vancouver island, where an explosion recently caused the death of 33 miners, have been re-opened.

BUTTE, MONTANA.

October Production.—North Butte and Tuolumne Dispute.

The mines of the Butte district are producing more copper at present than at any time since 1906, when copper stood at 25 and 26c. Every company operating in the district is producing at normal rate, and a few mines at capacity. Extraordinary development is also being done by the Butte Coalition, Anaconda, North Butte, Original, Trenton, Butte & Superior, Tuolumne, Butte-Ballaklava, East Butte, Davis-Daly, and Butte & Boston companies. Activity among the large and small companies indicates anything but fear as to the future of the copper industry. The production, in October, aggregates slightly more than 28,000,000 lb., the different companies contributing to the total as follows:

| Companies. | Copper, lb. |
|---------------------------|----------------|
| Boston & Montana..... | 8,100,000 |
| Anaconda | 6,700,000 |
| North Butte | 3,640,000 |
| Butte Coalition | 3,200,000 |
| Original | 1,670,000 |
| Butte & Boston..... | 1,200,000 |
| Washoe | 1,000,000 |
| Parrot | 675,000 |
| Trenton | 750,000 |
| Pittsburg & Montana | 610,000 |
| Davis-Daly | 300,000 |
| Miscellaneous | 220,000 |
| Total | 28,065,000 |

The North Butte Mining Co. expects to reach the Jessie vein in the 2200 cross-cut in about a week or ten

days. Some significant work is also being done on the 1600-ft. level in the Jessie ground, where a drift is being driven east as rapidly as possible. It is surmised that the purpose of this drift is, mainly, to prove the continuity of the vein and orebody from the Jessie vein and workings to the vein recently opened by the Tuolumne company at a depth of 1400 ft. Ever since the Tuolumne company cut into the rich vein on the 1400-ft. level north of the Tuolumne shaft, it has been asserted that the vein belonged to the North Butte and would be found to apex in the Jessie claim. A serious phase was given the dispute between the two companies when it became known that the North Butte company had quietly become owner of an interest in the Tuolumne ground. Unknown to the officers of the Tuolumne company an interest in a small fraction was outstanding and the North Butte purchased it. The purchase amounts to a three-eighths interest in an acre of ground along the northern portion of the Tuolumne claim. The latter unites with the Jessie of the North Butte company and when the two claims were located many years ago they slightly overlapped. The Tuolumne was the older location by about four days and its owners adversed the Jessie location. The result was a controversy and a division of the conflicting portions of the claims, but the portion in question went to patent as part of the Jessie, the Jessie owners then deeding half of it to the Tuolumne owners. By that transaction it did not, however, become part of the Tuolumne claim, but remained a separate parcel of ground, though owned by the same men that owned the Tuolumne patented ground. In the course of time a three-eighths interest, owned by Patrick Henry Meagher, a Montana rancher, was lost sight of and even he had forgotten its existence until a search of the record discovered the break in the Tuolumne's title. When it was discovered and brought to the attention of Mr. Meagher he offered it to the North Butte company which quickly bought it. This makes the North Butte company joint owner with the Tuolumne in the ground of the latter company. Under a statute of Montana, made to fit some phase of the mining controversy between the Amalgamated Copper company and F. A. Heinze, one owner of a mining property cannot work it without the consent of the co-owner, and as a co-owner the North Butte has the power to stop the Tuolumne from working its own property regardless of any question that may arise as to the apex of the vein being developed by the Tuolumne company. The officers of the latter claim they are not at all concerned about the action of the North Butte, and that the most cordial relations exist between the two companies. However, many stockholders of the Tuolumne cannot see wherein there is proof of cordiality in the purchase of the interest in the Tuolumne ground by the North Butte. They can see in it only the acquisition of a weapon, and whether of defense or offense remains to be seen. It is almost certain that the North Butte did not buy it as a souvenir.

MEXICO.

Zacualpan.—Magistral-Ameca Copper. — Castellane Con., Jalisco.
—El Mirado, Tepic. — Pachuca-Zimapan Railroad. — Sinaloa
Mining.—Oaxaca.

The owners of the Cuchara mill, near Zacualpan, in the State of Mexico, have been making extensive alterations to the plant. The last of the new concentrating tables are being erected, and the mill will soon be ready for operation. The work has been done under the direction of Mr. Newcomb, of the firm of White & Newcomb, of Mexico City, and under the immediate superintendence of Manager Chabaud. A considerable amount of American capital is invested in the enterprise, which is a silver-lead mine. The owners are making plans for the installation of a complete plant of power-drills.

The Magistral-Ameca Copper Co. owns the Magistral copper mines, about two hours' ride from Ameca, State of Jalisco. These mines were originally owned by Patsy Clark, but he finally turned them over to his nephew, J. P. Harvey, and associates, who formed the above company and raised sufficient capital to carry on the work. H. L.

Percy is president and J. P. Harvey is manager. The controlling company is incorporated with a capital of \$1,500,000, and the local Mexican holding company with \$100,000. They have now ordered a 150-ton reverberatory smelter. The concentrating problem has been a serious one, and an almost endless number of tests and experiments have been made. The Elmore flotation process has been under consideration, but the latest advices are that an ordinary wet concentration plant will be erected. The bulk of the low-grade ore averages about 3% copper, with a highly silicious gangue, but there is a considerable amount of rich sulphide ore, and the smelter will be installed in any case. Orders for the equipment have been definitely placed.

A Chicago company, incorporated with a capital of \$1,000,000, has taken over the Centralia mines in the Hostotipaquillo district of Jalisco. This property is close to the mines and mill of the San Felipe company, of Philadelphia, and arrangements will be made to treat the ores of the Centralia mines, for the time being, at the reduction plant of the San Felipe company. Samuel O. Morris is the manager in charge.

The Castellane Consolidated Mines, Ltd., of London, are the owners of 17 mines in the Territory of Tepic. They have been unwatering one of their properties, the old Guanajuatillo mine, but found that the vein was too small, and the orebodies were not of sufficient extent to warrant further expenditure of capital at the present price of silver. It is hoped that the Chapala Hydro-Electric & Irrigation Co. will run its power lines near the reduction-plant owned by the Castellane company on the Santiago river, and as soon as power is available the plant will be re-modeled and enlarged.

The Territory of Tepic is improving, so far as mining enterprise is concerned. Makeever Bros., of New York, are promoting the El Mirador Mining Co., with a capital of \$2,500,000. Of the stock of this company \$1,000,000 will be put into the treasury of the San Pablo Mining Co., another concern promoted by the Makeever Bros. The El Mirador Mining Co. will own the Mirador and San Francisco groups of mines, some of which were recently purchased from M. E. MacDonald, of Guanajuato. These mines lie north of the Santiago river, slightly west of the Bolaños. There are several 'antiguas' in the group. Sanford Makeever has recently been at the properties making arrangements for the beginning of operations. Air-compressors and drills are to be purchased and erected for the purpose of pushing ahead the development as fast as possible. The motive power to be used is to be steam, until the Chapala Hydro-Electric Co. extends its power-lines into the district.

The good showing made on the Tajo Mining Co.'s property with a 10-stamp mill has been sufficient to make the management decide to triple the plant next year, and to build an aerial tramway from the mines to the mill, a distance of 2600 ft. These mines are in the San Sebastian district of Jalisco. In the Ayutla district of Jalisco, the Los Aliles Mining Co. has found a rich body of copper ore on the Aguacate vein, and arrangements are being made to ship the ore to a smelter. Harry T. Curran is manager at the mines. The Chapala Hydro-Electric Co. is building its transmission lines north to the Hostotipaquillo district as fast as possible. The company is constructing an average of over one kilometre daily. The transmission lines are supported on iron towers 200 metres apart. The main distributing station will be at Hostotipaquillo, near the El Favor mine. A branch line will also be built to supply the Southern Pacific company with power for the tunnel work on the Tepic-Jalisco boundary. The Etzatlan mining district will also have a main distributing station.

There seems to be some possibility that Richard Honey, who is now backing the construction of the Pachuca-Zimapan railroad, will finance the concession held by the National Railroad of Mexico to build the line on to Tampico. This is known as the Tampico short line. Eighty kilometres of the roadbed were constructed from Tampico southward, but suspended about a year and a half ago. If Richard Honey and associates take up this work it will connect with the Zimapan-Pachuca line. The estimated cost of the line is \$17,000,000, for the Tampico extension.

This line would not only open up the Zimapan district, but would give a new outlet from Pachuca to the sea.

One of the very important companies operating in the Concordia district of Sinaloa is the Panuco Mining Co., a local concern, with headquarters at Mazatlán. They have been operating since 1877, and in the past 25 years have paid nearly \$10,000,000 in dividends. They are at present distributing an average of \$50,000 per month. The company can, therefore, be classed as one of the most prosperous in Sinaloa. The Butters Copala 40-stamp mill, which was started several months ago, has been averaging 250 tons per day, and it is the intention of the managers to steadily increase the output until 400 tons per day is reached, which is the full capacity of the mill.

The Cia. Minera La Natividad, of Oaxaca, has tried a novel method of closing some roads that crossed their property. They placed wire fences around the property and connected these up with a moderate potential electric generator, with the result that anyone interfering with the fences, or attempting to cross them, received a shock. This resulted in causing more trouble than the roads, as several dogs were killed, and the Indians protested to the Governor,

Part of Oaxaca, Mexico.

who is causing an investigation to be made. Two new American corporations have recently been formed for the purpose of entering the mining field of Taviche, Oaxaca. They are operating under the title of the Elisea Gold & Silver Mining Co. and the Two Brothers Mining Co. They hold options on several properties in the district. Oaxaca, the capital of the State of the same name, is to have modern water-works and a drainage-system. All of the plans are ready, but none of the material has been contracted for, as yet. The plant will consist of a large reservoir, with a capacity of 2,000,000 cubic metres, to be constructed at an elevation of 500 ft. above the city in the hills to the north. The supply is to be brought from Vista Hermosa, about 30 kilometres north of Oaxaca. The Teziutlán Copper Mining & Smelting Co. has had the good fortune to strike an entirely new vein in the new shaft, being sunk on the Ocotés claim. This is a copper property, but the new vein yields gold-silver ore, with hardly any copper. When the new railroad is completed to Taviche it will be possible to ship ores to the smelters, and in view of this, and of the development of high-grade shipping ores in the various Oaxaca

camps, F. R. Brown, representing the Aguascalientes smelter, has been making a tour of inspection, and has advised the company to establish a purchasing agency there. The Guebeshe mine, in the Ocotlán district of Oaxaca, has just struck a body of high-grade gold-bearing ore. Onyx mining in Oaxaca is assuming the proportions of an important industry. A. G. Hamm is in charge of the extensive development work being carried on at the onyx quarries at Etla. Further deep exploration work will be undertaken with a core-drill, that has just been secured. E. M. Lawton, the United States consular agent in Oaxaca, recently purchased some onyx properties and under his direction development has been begun and has already shown up a 30-ft. bank of green onyx. The deposit is from 6 to 8 ft. thick, and it is estimated that about 100 tons of available onyx is developed for every 5 ft. of advance. Core-drills are to be purchased and further deep prospecting is to be undertaken under the directions of Ingle Carpenter who has considerable experience in onyx work. It is stated that the San Juan mine in Oaxaca has been offered to J. H. Costello, of Buffalo, for \$500,000 as it stands, and if he refuses it at that price, it will be again offered to Denny Bros. on bond, subject to further development work, which it is said Denny Bros. are willing to carry on at their own expense. The Boston & Oaxaca Mining Co., owning the El Placer mine and mill, situated between Tlacolula and Oaxaca, has been in a state of internal dissension and trouble for some time, which ultimately resulted in forcing the company into the hands of a receiver. The property was

A Glimpse of Pachuca.

put up for auction at Pierre, South Dakota, and was bought in by Arthur P. Teele, for \$20,100. Teele is said to represent the Barnes-Cummings faction of the directors of the old company. Arrangements are being made to protect the shareholders who paid actual cash for their shares in the old company. The new combination will be freed from about 500,000 shares of promotion stock. Development is now to be pushed on the property.

A company has been incorporated in Zacatecas under the title of the Chalchihuites Mining Co. for working the Florencia, Ampliación de Milagros, and Felipe mines, all of which are in the Chalchihuites district, close to the Conjuro property. The incorporators and officers are: Milton R. Straight, president, New York City; Francis E. Agnew, vice-president, Chalchihuites; Cyrus A. Phelps, secretary, San José de Ranchos. The ore is silver-gold and the veins are partly opened. The building for the mill being erected by the Compañía Beneficiadora de Metales y Minerales de Zacatecas, is nearly completed. Machinery is arriving and the plant will soon be in running order. It will include concentration and cyanide plants. The company will undertake custom milling. The company was floated by native promoters and the State Government subscribed one-fifth of the stock. Engineer Velasco Peña is personally in charge of construction work.

The Allis-Chalmers Co. has seen fit to quote the Cia. Beneficiadora de San Francisco y Pachuca, for Pachuca tanks to be built in the United States, without regard to

patent rights in Mexico, and have guaranteed immunity against claims for royalty or damages. This means that the Allis-Chalmers Co. considers the patent invalid, and in regard to this it is an interesting fact that a conical type of tank with air agitation was illustrated in a catalogue dated 1905 of the Colorado Iron Works, which is prior to the date on which the patents were issued in Mexico. Francis E. Pratt, representative of the Hammond Iron Works, of Warren, Pennsylvania, has made application for a concession covering a period of ten years, for the exclusive right to manufacture iron tanks, pipes, and heavy sheet-steel work of all kinds, for mining, railroad, oil, and other industrial purposes, in the Republic of Mexico, and as there is practically no opposition it looks as though the concession would be granted. The invalidity of the MacArthur-Forrest patents was determined by the Mexican courts some time ago, and if cheap tanks and the termination of royalties, both come at the same time, there should be an increase in the number of cyanide plants.

WASHINGTON.

Secretary of the Interior on Reclamation.—Permissible Explosives.—

Arsenic and Bismuth Production.—Patents.—Panama Progress.

Richard A. Ballinger, Secretary of the Interior, has returned to Washington after an extended tour of the West. In a statement to the press he declared again that since his incumbency no water-power sites on the public domain have been secured by private parties, and that he has energetically made every effort, by temporary withdrawals, to segregate existing power-sites on the public domain, in order to enable Congress to legislate for their more prudent disposition. Respecting the reclamation work, the Secretary says the trip has inspired him with the ambition to complete existing projects as rapidly as business prudence and money available will permit, and he is earnestly in favor of securing authority from Congress for the issuance of bonds against the Reclamation fund, to give the service the means whereby all existing projects can be speedily completed and necessary extensions taken. He was emphatic in his commendation of the personnel of the service and of the high type of construction for which they are responsible. In his annual report, the Secretary will place special emphasis upon the right use and disposition of the coal, phosphate, oil, and other mineral deposits. The activities of his department, the Secretary says, will show an aggressive and untiring effort to prevent the illegal and improper disposition of the public domain.

Explosives Circular No. 2, dealing with permissible explosives for use in coal mines, has just been issued by the United States Geological Survey. Altogether 31 explosives have passed the test at the testing station at Pittsburgh, Pennsylvania. So far, three coal mining States, Pennsylvania, West Virginia, and Alabama, have adopted the use of these permissible explosives in gassy mines. In Pennsylvania there is a little difficulty. The miners in the Pittsburgh district claim that the 'permissible explosives' make more fine coal than the black powder, and that their earnings are thereby affected. Many of the miners expressed themselves as satisfied with the use of black blasting powder. Some of them doubted that explosions were ever caused by coal dust. Mr. Tom Lewis, president of the United Mine Workers of America, has been in Pittsburgh attempting to settle the dispute, and he suggested a visit to the Government experiment plant. This was arranged, and before the men left the plant, all had a vivid idea of the force of a coal-dust explosion ignited by black powder. What makes the dispute between the miners and operators difficult to settle is the fact that the operators have let contracts for their coal based upon the scale of wages agreed upon before the question of permissible explosives arose.

During 1908, according to F. L. Hess, of the U. S. Geological Survey, arsenic was produced in a commercial way at only two places in the United States—Everett, Washington, where the American Smelters Securities Co. has a plant, and at the Washoe smelter, Anaconda, Montana. The product was in the form of white arsenic (arsenic trioxide), and was derived largely from flue-dust. If even one-half

the arsenic that passes up the flues of the Washoe smelter could be saved, that plant would more than supply the whole demand in this country for arsenic and its compounds. The United States has been a small producer of bismuth ores, and until the last two years these ores have been shipped abroad for reduction, but plants at St. Louis, Missouri, and Grasse, Indiana, are now recovering bismuth from lead ores. Bismuth is contained also in ores of other metals than lead, but most of it that is now mined passes unrecovered out of the smelter flues. It is estimated that 880 lb. of bismuth are thrown off every day in the smoke and gases of the Washoe smelter.

A. Platt Andrew, the new Director of the Mint, has arrived in Washington to take up his new duties. He has been abroad with Nelson W. Aldrich, Senator from Rhode Island, studying the financial situation in connection with the monetary commission, and will go West with Mr. Aldrich to try to educate the Western States up to acquiescence in Mr. Aldrich's plan of currency legislation. The Patent Office here in Washington shows that 900,000 patents have been issued to citizens of the United States since the creation of this office. More than 2,000,000 foreign patents have been recorded here. During the year 1908, 35,000 patents were issued. The grand total of receipts over expenses in the Patent Office since its establishment is \$7,060,547. During the month of September, 2,771,245 cu. yd. were excavated in the construction of the Panama Canal; 420 tons of explosives were used; 19,417 men were employed.

GOLDFIELD, NEVADA.

Ore Production.—Consolidated Mines Ore Reserves. — Red Top. — Florence Output.—Combination Fraction.

Ore production is maintained at a figure slightly above \$200,000 per week in the Goldfield district. This is below normal, owing to the abandonment of the Combination mill, a portion of which was demolished by the caving of the Hampton stope, and the suspension of operations on the Goldfield Daisy. Within less than 90 days the output will be increased by the installation of Chilean mills in the Consolidated company's 100-stamp mill, increasing the capacity of that plant to a minimum of 850 tons per day, and at least three leases in inside territory, on which deep shafts are being sunk near proved orebodies, should, from present indications, be sending ore to the samplers. The report of the State bullion-tax agent, just issued, for the first six months of the present year, shows that Esmeralda county produced nearly five-sixths of the mineral value of the State, and that the Goldfield Consolidated Mines Co. paid a larger sum in bullion-tax than all other mining enterprises in the State combined. The gross production of Nevada for the first six months of 1909 is \$13,234,692, as against \$5,838,161 for the corresponding period in 1908, and the bullion-tax paid for this period was \$121,512, as against \$45,519 for the same time last year.

An examination of the mine workings and office records of the Consolidated Mines Co. shows that the ore reserves have been materially augmented during the past few months, and by far the most valuable development in the mine is the opening at the 600, 730, and 860-ft. levels of the Mohawk-Jumbo ore-shoot, which is now conceded to be superior even to the Hampton vein of the Combination. The accuracy of the figures and assay values quoted is confirmed by H. P. Henderson, general superintendent. At the 1000-ft. level of the Clermont progress has been slower owing to the character of the ground and the heavy flow of water, but the sump is 50 ft. below this level, and a high-power electric station-pump has eliminated this difficulty. The west cross-cut is being driven rapidly, though it is not expected that the vein will be reached for over a month. The 860-ft. cross-cut passed through the vein diagonally, showing 20 ft. of high-grade milling ore accompanied by seams of richer material, and the drifts both ways have opened the vein for over 260 ft., all in ore. The trend of the vein at this depth is the same as that shown above, namely, northeastward, with marked uniformity of wall.

The most notable development is at the 730-ft. level from the Clermont, where the cross-cut became a drift in ore for over 250 ft., and at the point where the vein was cut through, the samplings of the face of the cut for 27 ft. across the vein assayed from \$500 to \$2200 per ton. At this point a raise was started to the 600-ft. level, but the entire mass of the ore was of such richness that the raise was abandoned, and work started in material of lower grade in order to break ore nearer in value to the desired grade for treatment in the mill. One raise has already been completed from the 730 to the 600-ft. level, and is all in good ore. The vein has been followed 60 ft. farther, and for the entire distance shows large quantities of high-grade ore. Within a month another raise will be started to meet the drifts from the bottom of a winze sunk 50 ft. below the sill-floors of the great stopes at the southeast corner of the Mohawk, extending into the Jumbo, which are opened between the 450 and 600-ft. levels. Large bodies of high-grade ore are being developed in ground adjoining the long cross-cut connecting the Mohawk and Clermont shafts at the 600-ft. level. This cross-cut was driven in a direct line from the Mohawk workings to secure air-connection and without regard to the position of orebodies, and for over 300 ft. east of the Mohawk workings it passes through quartz, after which it enters the country rock. A large production is being made from the big southeast stopes of the Mohawk, and excellent ore is being opened in drifts from the winze, 50 ft. deeper. The northwest lateral from the Clermont at the 600-ft. level has entered the Red Top vein on the Lucky Boy claim, and drifts are following the ore both ways. The vein was cut at the point where it turns sharply to the west and below the best stopes in the Red Top vein. After its turn to the west this vein apparently becomes a part of the Mohawk, both being, in point of fact, parts of one great vein system, but there is a short interval where the ore is not proved at the junction of the two main veins, and where a large fault has caused a break in the continuity of the ore, which, however, extends to the fault-planes on either side.

A steady production is being made from the long series of stopes in the Red Top vein north and south at the 260-ft. level, and the vein is being opened extensively at the 330-ft. level. Pay-ore has now been opened in this vein almost continuously for a distance of 1600 ft. north and south, and the Red Top drift north has connected with the stopes of of the former Consolidated Red Top lease, and has exposed high-grade ore within a few feet of the lease workings. Ore of excellent quality is being taken from the Combination mine, and the caving of the Hampton stope will cause but little interruption in ore extraction. The superintendent says it is still uncertain how much of the caved material can be treated profitably, as a large part of this is country rock from the hanging wall. A force of miners is still engaged seeking the bodies of the two men entombed by the falling ground above the big stope. At the south end of the Combination No. 1 and on the Combination No. 2, adjoining the old Reilly lease on the Florence, large stopes have been opened at the fourth level and are now being opened at the fifth. The work of 'glory-holing' this vein and opening it to the surface will be deferred until the additions to the mill shall have been completed, but raises will soon begin from the stopes below.

The Florence mine is producing, and the mill treating, nearly 160 tons per day, and the mill-heads are averaging between \$25 and \$30 per ton. Stopes are being opened at several points, but the principal production is still from development work, and a large part of the tonnage comes from the Little-Florence shaft, whence it is conveyed by aerial trolley to the mill-bins. One of the most important developments is at the fourth level near the former Gem Florence lease workings, where the ore is being stoped for a width of from 10 to 14 ft. between well defined walls, the entire orebody assaying from \$50 to \$100 per ton, with seams and pockets of rich telluride. There is now a large tonnage of high-grade ore exposed in the mine and blocked in readiness for extraction. Shipments can be made at short notice if desired. Other good orebodies are opened at the fourth level in the Engineers' vein, where the ore assays from \$60 to \$100.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The Empire shaft, at Dragoon, is down over 100 ft., and has opened a 5-ft. vein. Colorado capitalists have secured a ten days' option on the property, of which Oliver Merrill is superintendent. Mr. Merrill and associates have located a group of claims three miles from Cochise and have taken a number of samples from the property, the average assay of which was 14 oz. silver, and \$16.50 gold per ton.—The Mabel Copper Co. is to install a compressor and power plant at its property in the Dragoon mountains, and will shortly commence work on a 1000-ft. adit that will open the orebody at depth.

GILA COUNTY.

The Superior & Boston Copper Co. has completed a station on the sixth level of the McGaw shaft, and is cross-cutting for the Great Eastern vein which is several hundred feet west of the shaft. On the 400-ft. level of the Gardner shaft the cross-cut is being driven to open the Black Oxide vein. The company is erecting a change house for the men north of the McGaw shaft that will be one of the best in the district when completed.—The Scorpion shaft of the Inspiration Copper Co. is down 150 ft. and is expected to cut the sulphide zone shortly. Both cross-cuts on the 400-ft. level of the Joe Bush shaft are in ore, the face averaging 3% copper. The company has completed 15 holes with two Keystone drills and is now erecting a number of cottages for its employees.—At the property of the Cole Development Co., near Gibson, the shaft in which work was resumed several weeks ago at a depth of 320 ft., is now down 340 ft., the bottom being in an ore that is chiefly chalcopryrite, and assays between 8 and 10% copper.—The new smelter of the Arizona Commercial Copper Co., which was blown-in October 15, is running successfully, treating 200 tons of ore per day. The supply is being drawn from the fifth and sixth levels of the company's property at Copper hill, and the Copper Bell mine. The station at the seventh level of the Eureka shaft has been completed and drifts started on the vein. A heavy Prescott station pump is to be installed on this level to handle the heavy flow of water during the wet season.—On the 200-ft. level of the Live Oak property, in the Miami district, the west cross-cut is in a concentrating ore that averages 2% copper, and on the 300-ft. level, the work has been extended over 360 ft., the present face being in 3% ore. At the Cordova property the cross-cut has been driven 40 ft. on the 475-ft. level. There is a fair showing of chalcocite in the face and the company expects to open a body of commercial grade within a short distance. M. E. McCarthy is manager of both properties.—Considerable surface work is being done at the Duquesne property, near Globe, to ascertain the best place to sink a vertical shaft, as the company plans the erection of a new surface plant. A number of recent shipments to the Old Dominion smelter recently averaged 2 oz. gold per ton. John F. Shaw is president of the company.

MOHAVE COUNTY.

The Union Basin Mining Co. shipped seven cars of zinc ore to the smelter that assayed 45% zinc.—A new tubemill has been installed at the Tom Reed mine at Oatman and the mortars are being set in position.—A wagon road has been completed to the Bethel mine, in Todd basin, which was recently taken over by L. D. Godshall and associates. There is a large outcrop on the property and it is the intention of the owners to sink a shaft to open the ore. The same parties have secured the controlling interest in the Oro Plata mine and it is reported that operations will be resumed at that property in a short time.—James H. Hurin, of Los Angeles, president of the Tennessee Mining Co., is now in Chloride examining the company's property with a view to unwatering the mine and resuming operations. The Tennessee mine, which is opened by a 600-ft. shaft and several thousand feet of drifts, though idle for the past two years, has produced in the aggregate more than

any mine in the Chloride district. The vein is from 6 to 12 ft. wide, and on the lowest level the last work opened a 300-ft. shoot.—In the Cottonwood district, eight miles from Hackberry, James Brown has cut 2 ft. of \$60 free-milling gold ore in the bottom of a 20-ft. shaft, and in the same vicinity McAbee & McBride have opened at a depth of 50 ft. 4 ft. of ore of the same character, 18 in. of which assays a little over \$60 per ton, the remainder being a good grade of milling ore.—In the Southwestern mine, at Copperville, 22 miles from Yucca, 4 ft. of ore has been found on the 300-ft. level. The ore contains chalcopryrite, gold, and silver, with the light quartz gangue. As a result of the new find, sinking will be resumed at once, and the shaft continued to the 500-ft. level.—A. C. Werden, representing Denver capitalists, has started sinking on the Paddy Mullen property, near Goldroad, which he bonded recently. Mr. Werden is also preparing to install machinery on the Red Creek group adjoining the Gold Road mine on the north.

YAVAPAI COUNTY.

The Thompson Syndicate, which has recently taken over the Leghorn group, in the Cherry Creek district, has let a contract to sink a 200-ft. shaft and drive 400 ft. on the vein. The property is to be equipped with a Lane mill, and new living quarters erected for the men.—The Mudhole mine, in the Walker district, operated by the Penn-Arizona Mining Co., has been unwatered and a new electric hoist erected at the shaft. The mill on the property has been repaired and will now be driven by electric power as connection has been made with the lines of the Arizona Power Co. A. E. Hurley is manager for the company.—There are several tons of rich ore on the dump of the Champion mine which John Edwards is operating on a lease.

CALIFORNIA.

KERN COUNTY.

The well of the St. Lawrence Oil Co., in the Midland district, struck a flow of light oil at a depth of 1760 ft.—The Santa Fe company, drilling in the same district, has brought in a well of light oil. The flow was so heavy at first that it was impossible to control it and several hundred barrels escaped before the well was capped.—A meeting of the stockholders of the Two-Step Oil Co. has been called for November 10 to organize the Walker Oil Co., which will take over the property of the Two-Step company in the Devil's Den district.

NAPA COUNTY.

The old Aetna quicksilver mine has been re-opened and 17 flasks of quicksilver shipped in the past three months. There is considerable ore blocked out in the mine, but only one small retort has been put in operation.

NEVADA COUNTY.

The Kenosha mill has been started on ore from the shoot

Vein From Head-Frame of Empire Shaft.

recently opened in the north drift on the 400-ft. level and sinking resumed in the shaft.—At the Idaho-Maryland the raise from the 600 to the 500-ft. level is opening some rich ore. The drift on the 500-ft. level is in a good milling ore

and a fair tonnage is being sent to the mill from the intermediate level above the 400.

PLACER COUNTY.

(Special Correspondence).—The Ophir district is taking on new life. Several deals of some importance have been recently made, and a number of properties that have lain idle for years, are to be re-opened, among these being the Hathaway, formerly one of the great producers of the county.—New machinery has been installed at the Crater, which is being worked by lessees, with good results.—It is reported that the Crandall mine has been purchased by Colorado capitalists, and will be further developed.—At Michigan Bluffs, W. S. Fletcher is preparing to resume work at the Home Ticket. This property was recently closed because of a strike of the miners, but the trouble has been adjusted.

Auburn, November 1.

RIVERSIDE COUNTY.

(Special Correspondence).—A large vein of free-milling ore assaying \$50 per ton has been opened at a depth of 100 ft. on the Bailey group.—Operations have been resumed at the Elder Morn and shipping will commence with the completion of the railroad.—At the Rapynco a 4-ft. vein, said to assay \$100 per ton in copper, gold, and silver, has been opened in the new adit. A station will be cut at this point and a shaft sunk on the vein.—At the Steece group a good reserve of ore has been opened assaying from \$10 to \$50 per ton. It is possible that a plant will be erected next year.—In the Whipple district activities are pronounced. A deal for the Hon is under way, and is expected to be concluded within a few days.—The D. & W. and others are showing good ore with increasing depth. Owing to lack of capital the properties in this district are operating on a restricted scale.

Calzona, October 30.

SIERRA COUNTY.

The drift at the Rainbow Extension mine in the Alleghany district opened a shoot of high-grade ore that will assay several thousand dollars per ton. The property is situated between the Rainbow and Twenty-One mines, and is thought to be on the same lead. The drift is now in 160 ft., and has been in the rich shoot for the last 20. A raise has been started and is now up 15 ft. O. A. Harlan is manager.—At the Gold Canyon mine considerable rich ore is being mined and the 10-stamp mill is running regularly. A new adit is to be started soon to open the ore at greater depth. R. H. Chase is superintendent.—M. H. Miller has secured an option on the Round Lake property of Dan Sullivan and Tony Lavezzola, and will commence work in the spring.—It is reported that operations will be resumed at the old California drift at Howland Flat.—At the Hilo gravel mine, on Chaparral hill, the Bernhardt Brothers are driving a raise to the surface for ventilation.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—Shipments of milling ore are to be started next week from the Mammoth mine on Sherman mountain. B. J. Martelon, the manager, states that arrangements have been made with the operators of the Mendota mill to treat 25 tons of lead-zinc ore per day. The Argentine Exploration Co., operating this property, expects to start work on the construction of a concentrating plant within the next 60 days. The initial capacity is to be 25 tons per day.—The raise from the east drift on the Gambetta vein to connect with the old shaft workings was completed last Saturday. The entire 220 ft. being in lead-zinc ore that is from 8 to 20 in. wide. The zinc from this mine is the cleanest and highest grade found in the State, milling on an average of 56%. B. J. O'Connell, the manager, states that a compressor-plant will be purchased about January 1.—Another vein of lead-silver ore was cut last week on the Bellmont property, owned by the Empire Consolidated Mining Co., that assays 550 oz. silver per ton.—M. Bonham, owner of the North Star property, situated in East Argentine, has resumed work.—J. Eade has taken a lease upon a block of ground on the Wheeling vein.

Shipments of \$18 gold and silver-bearing ore are being made to the Waldorf mill.

Georgetown, October 30.

(Special Correspondence).—The Specie Payment mine in Virginia canyon, is shipping 50 tons per day, the return on which is 7 to 10 oz. gold per ton. A. M. Wells, of Denver, is manager.—All repairs at the Josephine mine, on Donaldson mountain, have been completed and the 100-ton mill started, the power being furnished by the Seaton Mountain Electric Co.—Shipments are to be started during the coming week from the holdings of the Philadelphia Mining Co., on Bellevue mountain. On the Boston vein a streak of lead ore has been followed for 400 ft. that is from a few inches to 2 ft. wide. The adit is to be continued for at least 1500 ft. to intersect the Grouse mines at depth. J. W. Boyd is manager.—The new Mixwell mill has been completed and will be started in a few days. The plant is constructed for amalgamation and concentration and is one of the most complete in the district. Philip Mixwell is manager.—H. I. Seemann, manager of the Lombard mines, states that work will be carried on throughout the winter months though, owing to lack of water, the 50-ton mill has been closed down for the season.—It is stated that within a short time work will be resumed in the advance of the Lucania adit, on Bellevue mountain. John McCall is manager.—The Stevenson lease, on the Little Mattie mine, on Chicago mountain, is proving one of the richest in this district. A body of ore is exposed in the stope that is from 8 to 20 in. wide, and the return on shipments has been 6.4 oz. gold and 37 oz. silver per ton.

Idaho Springs, October 29.

GILPIN COUNTY.

(Special Correspondence).—The shaft on the Chicago-Star property on Bobtail hill is to be sunk another 80 ft., making the total depth 800 ft. All work at the mine has been carried on by lessees, and the average return on the smelting ore varies from 2 to 3 oz. gold per ton. The mine is owned by Bruce Meyers, of Chicago.—A Rand compressor has been purchased by T. B. Bassett, who is operating the Baker mine through the La Crosse adit.—Preliminary work is under way on Fall river for the building of a large power plant during the coming year, the work on the dam and ditch being nearly completed.—Machinery has just been installed at the Rockford mine in Russell gulch, and the shaft will be sunk to the 240-ft. level, arrangements having been made to secure air from the Topeka power plant to operate machine-drills. This property was purchased a few months ago by H. P. Lowe and S. T. Harris.—The Golden Flint mine, at Perigo, was the scene of an important discovery a few days ago, a body of ore from 2 to 3 ft. wide having been uncovered that assays from \$17 to \$24 per ton. A 60-hp. boiler is to be installed.—The Aduddell mine, in Willis gulch, is to be started during the coming week. An examination of the workings shows that they have been drained by the Newhouse tunnel.—Operations have been resumed on the Gold Collar mine in Prosser gulch and grading is under way for a new 100-hp. boiler.—Frick, Taylor & Co., of Black Hawk, have resumed work upon their lease on the Milton mine. The shaft is being unwatered and will be sunk another 75 ft.—The property of the Jefferson-Calhoun Mining Co. was sold last week at sheriff's sale for \$35,000, while the holdings of the Calhoun T. & M. Co. were sold for \$20,000. The property was bid in by F. A. Williams, who serves as trustee, and it is reported that the holdings will shortly be redeemed.

Central City, October 26.

OURAY COUNTY.

The Revenue Tunnel Mines Co. has taken over its property in the Ouray district from the lessees and is operating it on company account. In the mill 30 of the 60 stamps are dropping on 100 tons of ore per day.—Operations have been resumed at the El Mahdi property which is under lease to F. H. Herzinger. A 300-ft. shaft has been sunk and several laterals run. A raise will be started on a streak of rich ore on the adit level and if the ore exposed warrants further work, the shaft will be cleaned out, and

work resumed there.—Fifty feet have been driven on the new level at the Chicago property and 150 sacks of rich ore stored on the dump. This property is under lease to Cripple Creek parties and is in charge of T. Crowley.

SUMMIT COUNTY.

The shaft at the Sallie Barber mine is to be sunk an additional 100 ft. and the ore blocked out on that level. The shipping ore at this property is mainly composed of zinc blende.—At the White Cloud property the mill is running on ore that averages \$18 per ton.—The Wellington property is shipping regularly and in a short time is to begin shipping concentrate to the sulphuric acid plant.

TELLER COUNTY.

The May Belle Leasing Co. has been organized to operate the May Belle property upon which it has secured a lease from the Victor Mines & Leasing Co. The company will install new machinery and open the mine from the 400-ft. shaft on the property.—The Elkton Consolidated Mining & Milling Co. distributed the regular bi-monthly dividend of 1c. per share and an extra dividend of 1/2c. per share, the total amount being \$37,500.—The Victor Consolidated Gold Mining Co. distributed the regular quarterly dividend of 3c. per share amounting to \$45,000.—The Union Leasing Co., operating on the 550-ft. level of the Husted shaft, opened a 4-ft. vein east of the shaft that assays between \$15 and \$50 per ton. The company is producing two cars of ore per day.—The Keener Gold Mining Co. has installed a new hoist and two 100-hp. boilers at its property on Battle mountain and is blocking out the ore preparatory to opening it for leasing.—The Colorado Mines Investment Co. shipped 30 tons of high-grade ore from the shoot recently opened on the eleventh level of the American Eagles mine which it is operating under lease.

IDAHO.

SHOSHONE COUNTY.

The Illinois Western Concentrating Co. has been organized to work over the tailing from the Morning mine at Mullan, and arrangements are under way for the installation of a mill in the creek-bed west of the property, the cost of which is estimated at not less than \$30,000. The project is being financed by a Chicago syndicate, the local representative being O. H. King.—The Alice Mining Co., operating between Wallace and Mullan, has completed arrangements to ship its first ore. The mill is working eight hours per day with good results and the development of the lower levels is progressing steadily.—It is announced that the old antimony mill, 15 miles east of Burke, which has been closed for 17 years, will resume operations in a short time. The property was opened by several adits, large bodies of antimony ore being exposed, and a smelting plant erected. This was not a success, however, and a new one will be installed.—The Bunker Hill & Sullivan company's new west mill, at Wardner, is to be in operation early this month. It has a capacity of 600 tons per day, and embraces all of the latest features in the thorough and economic handling of lead-silver ores. The power is derived from two motors of 200 and 250 hp., the current being supplied by the Washington Water Power Co., of Spokane. The east mill is to be partly shut down for repairs.—Grading for the new mill at the Black Horse mine, near Murray, is completed, and the machinery ordered, though it is not expected that the plant will be in operation before next spring. On the lower level the ore-shoot has been exposed for 200 ft., much of which is of a shipping grade, while the rest is good milling ore.—The mill at the Monarch mine, near Murray, which is being enlarged to 200 tons per day capacity, will be completed the latter part of this month. A long raise has been driven from the 800-ft. level to the surface and an excellent body of ore opened.

IDAHO COUNTY.

The Mines Company, Ltd., operating the Crackerjack property in the Buffalo Hump district, has secured control of 282 acres of patented ground adjoining its claims on a 50-year lease. A 3000-ft. aerial tram is under construction from the mine to mill and the company expects to have the plant in operation by the first of the year. The

management is making a number of experiments to determine as to the advisability of cyaniding the concentrate on the ground or to continue shipping it to the smelter.

NEZ PERCE COUNTY.

The cross-cut adit of the Ozark Mining Co., operating the Wild Rose mine in the Pierce district, intersected the vein at a vertical depth of 587 ft. A meeting of the stockholders is to be held at Pierce shortly to consider the advisability of continuing work throughout the winter and later erecting a mill on the property.

MISSOURI.

NEWTON COUNTY.

(Special Correspondence).—In the U. G. Wilson mine, in Spring City, a winze was sunk through a barren stratum and some rich ore found.—The Silver Dime Mining Co. has made a rich lead discovery on the O'Neil land east of Spurgeon. The ore occurs at 90 ft.—A new discovery resembling the early day silicate finds, was made by P. H. Crossman, west of Granby. The ore is high-grade and is found at a shallow depth.—The Mascot and Homestake, in the Granby camp, have gone below the usual level and opened a deposit of rich zinc blende at 235 ft. with a face 45 ft. high. The usual type of ore in this camp is silicate at a shallow level with considerable galena.—Many companies are at work in the Seneca camp in the southern part of the county.—The Lost Creek Co. has reached the best stage of development and is erecting a large plant. Silicate and galena predominate.

Seneca, October 30.

MONTANA.

LINCOLN COUNTY.

The Fisher Creek Mining & Smelting Co., which recently took over the Brick & Branagan properties on Fisher creek, 35 miles south of Libby, is to enlarge the 10-stamp mill and equip the mine with electric power. Arthur Goodwin is in charge of the work.

NEVADA.

ESMERALDA COUNTY.

Company work at the Daisy property has been entirely suspended, and most of the officers have tendered their resignations. John C. Kinnear will be in charge of the mine while the lessees continue operations.—A raise started from the 730-ft. level of the Consolidated ground to connect with the Clermont workings has opened a shoot of high-grade ore, and work at this point has been stopped and another raise started in a lower-grade ore to keep the product for the mill of even grade.—The Coming Nation Mining Co. has been re-organized and consolidated with the Eagle group as the Goldfield Consolidated East Extension group.

CLARK COUNTY.

(Special Correspondence).—The New Year's Gift has installed a new hoist and within a short time will be working from the winze below the 130-ft. level. The shipping ore will be sent to smelters, and the low-grade handled by the Chiquite mill, which is to be removed from Juniper to a site near the New York-Searchlight. Water will be obtained from the latter mine.—Lessees on the I X L have broken into a body of milling ore, though the extent of the vein is undetermined.—The New Year's Gift vein has been cut on the 600-ft. level of the Fraction property, but is very low-grade.—The shaft at the Searchlight Owl has reached a depth of 45 ft., cutting stringers of good ore at the 25 and 35-ft. points. The shaft is expected to intersect the Red Cliff vein at depth. A. J. Lawrence is superintendent.—The 40-ft. adit at the Colleen Bawn has cut a 3-ft. body of ore assaying \$40 per ton gold, silver, and lead. It will be driven 100 ft. farther, which will give nearly 150 ft. of stoping ground. Williams Reynolds is in charge.—A vein varying from 3 to 40 ft. in width and assaying from \$2 to \$20 per ton in gold and silver is being opened on the San Juan group. Eckerson & Miller report the striking of a 12-in. streak of ore assaying 200 oz. silver per ton, near Crescent.—Several companies are operating on turquoise properties at Crescent. The deposits are shallow, but many fine stones have been taken out.—At the C. & C. mine a

vein of self-fluxing ore containing gold, silver, copper, and lead is reported.—El Dorado canyon operators are constructing a wagon-road to this point to facilitate the shipment of machinery and supplies. The main shaft of the Lenape Gold & Copper Co. has struck a small flow of water at a depth of 290 ft. Cross-cutting will soon start from the 300-ft. point.—The Quartette Jr. will commence work on four claims adjoining the Quartette within a short time. T. J. Randall is manager.

Searchlight, October 29.

LINCOLN COUNTY.

The cross-cut on the 800-ft. level of the Mendha mine, in the Ploche district, opened a new orebody 325 ft. from the shaft. This is in territory that has never been prospected before so the extent of the discovery is unknown. On the 900-ft. level the winze is down 25 ft. on a 5-ft. vein that assays \$15 gold, 30 oz. silver, and 28% lead. John R. Cook is manager.—At the Black Vault mine the inclined shaft has opened some extremely rich ore, the average assaying over \$100 per ton in silver and lead. Alex Colbath is superintendent.—At the Consolidated Ploche properties the officers of the new company are planning the erection of a complete plant for the treatment of the lead-zinc-silver ore. It is expected that work will be started on this about the first of the year.

LYON COUNTY.

The 50-ft. shaft of Ross Thompson opened a body of chalcocite ore on his claims adjoining the Mason Valley

from the entrance. The inclined shaft on the Pettibone claim is down 36 ft. on the vein.—Several small transfers in placer properties at Manhattan have been recorded, Eastern people becoming interested.—In a battle between high-graders at the Stray Dog and a number of officers a few nights ago, Mr. Martinson, deputy sheriff, was wounded. The robbers descended to the 320-ft. level and were hard at work when detected. They escaped in the darkness, but it is believed that one of them was badly wounded.—Clothier & Gingles have uncovered a 12-in. streak of \$50 ore on Tramps Consolidated ground and the Kilker-O'Connor lease has opened milling ore.

Tonopah, October 23.

WHITE PINE COUNTY.

(Special Correspondence).—Driving has started from the 400-ft. level of the Brilliant shaft on Ely Consolidated to explore a cross-fissure recently intersected in the contact. Owing to the flooding of the lower levels no work is progressing below this point. The new vein is said to run 4% copper, \$5 gold per ton, with slight traces of silver. S. M. Levy is manager.—The raise from the 1000-ft. level in the new shaft at the Giroux is about 450 ft. from the surface. Progress has been at the rate of 150 ft. per month. The shaft is five-compartment and is in limestone. Concrete foundations for the new hoist are being placed in position.—The shaft at Boston-Ely has passed the 1000-ft. point and is going down rapidly. From the 600-ft. level it has been in the oxidized zone. Small streaks of copper are showing in the bottom of the shaft. E. W. Ralph is superintendent.—The fourth reverberatory at Smelter is in commission. This will enable the management to conduct repairs on one of the older furnaces without reducing the monthly output. The steam-shovels at Copper Flat continue to maintain a production of 10,000 tons.

Ely, October 27.

NEW MEXICO.

GRANT COUNTY.

Phelps, Dodge & Co. have purchased the properties of the Burro Mountain Copper Co., at Leopold, from Nathan Leopold, of Chicago. There are 1000 acres in the property which is traversed by several rich veins as well as containing a large low-grade porphyry deposit. From these ores some 12,000,000 or 15,000,000 lb. of copper has been smelted. It is the intention of the company to open the mine gradually to supplement the output from its other properties.

SIERRA COUNTY.

(Special Correspondence).—Sinking has been resumed at the United States Treasury mine and a cross-cut will be extended from the 200-ft. level to tap the main orebody. This is about 4 ft. wide and assays \$20 to \$30 per ton, the ore carrying considerable silver. The new plant of machinery has been installed. The Keystone has been taken under lease by B. L. Morrison, of Colorado Springs, and will be energetically developed. The vein outcrops on the surface for a considerable distance and varies from 4 to 12 ft. in width. Considerable ore has been opened by lessees who expect to maintain a production of 50 tons per day. The assays are from \$8 to \$12, with a small streak running as high as \$100 per ton.—The cross-cut on the Keepsake claim of the Great Republic has intersected the extension of the Keystone vein, which is 3 ft. wide at this point.

Chloride, October 30.

OREGON.

JOSEPHINE COUNTY.

The Oregon-California Consolidated Mines Co., with headquarters at Grants Pass, has installed hydraulic equipment at the former Briggs property near the Oregon-California State line, built living quarters for the men, and will work the placer ground of the group. The property has had a rather meteoric career, the outcrop of a rich vein being accidentally discovered by a hunter who sold the ground to

Searchlight, Nevada.

property.—Owing to the delay of a shipment of track bolts and spikes the progress of the Copper Belt railroad to Yerington has been somewhat delayed. A large amount of freight is stored at both terminals awaiting the completion of the road.

NYE COUNTY.

(Special Correspondence).—Approximately 6000 tons of ore are on the dumps of the West End company and 1000 more are stored in the stopes assaying about \$14 per ton. The company is negotiating for the steady treatment of its ore at a local plant.—The MacNamara is producing 500 tons of ore per week. Explorations are under way at the 800-ft. point, but no stoping is being done below the 200-ft. level. Gold ore has been opened on the 300.—The Dougherty lease on Jim Butler continues to ship steadily.—The Cooper & Nagle lease at Ellendale is said to have cut a 2-in. streak of \$500 ore at a depth of 50 ft. A larger vein of milling ore is being prospected.—With the exception of this discovery there has been little of interest at Ellendale since the first shipment, valued at \$27,000. Many of the first comers have departed for other points.—Work will be resumed at once on the Nevada company properties near Sodaville. The main orebody has been cut on the 800-ft. level of the Round Mountain mine, the ore assaying about \$10 per ton. The September production was \$34,000.—A 4-ft. vein running \$15 to \$20 per ton has been struck on the Haywood claim of the Buckeye Mining Co. at Manhattan. The find was made in the adit, 128 ft.

local capitalists for \$140,000, these in turn disposing of it to Eastern people, who a short time ago bonded the claims to the Oregon-California company. The company plans to erect a mill in the near future, as several adits which have been driven to cut the vein are all in good milling ore. The company has also secured properties near Gold Hill and Jacksonville. George W. Soranson will be in charge of the company's Western affairs.

PHILIPPINE ISLANDS.

The August yield of the Benguet Consolidated Mining Co. was \$5000 on the plates and \$3500 from the cyanide plant, the total product for the first seven months being approximately \$40,000.—In the Aroroy district the Tenco Mining Co. has opened a shoot of \$20 ore on the Mount Cogran company's property. There is a 10-stamp mill on the ground and this is to be re-modeled shortly and started as soon as the company has enough ore blocked out to keep it run-

cide to use it for dividends, it will amount to approximately 30c. per share.—E. C. Loose, of Provo, has obtained the controlling interest of the Ajax Mining Co., and the Golden Chain that adjoins it, and will consolidate the two properties, working them through the Ajax shaft.—The shaft at the East Tintic mine, in East Tintic, is down 515 ft., with a station cut and cross-cuts started on the 500-ft. level. The drift on the 330-ft. level is being advanced and the company is shipping three cars of ore per day from the 230-ft. level.—At the Provo, adjoining the East Tintic, the cross-cut opened ore thought to be the extension of the Tintic company's vein.—The drift on the 200-ft. level of the Grutil has opened several small bunches of ore and it is expected to tap the main orebody shortly.—The shaft of the Tintic Standard is now down 620 ft., and a contract has been let to sink it to the 800-ft. level. It is thought that at this depth the workings will be below the leached portion of the deposits.

SUMMIT COUNTY.

The cross-cut on the 1550-ft. level of the Silver King Consolidated property opened a rich stringer of silver-lead ore with some copper and gold. This ore was found in a fissure in the quartzite and a raise has been started to intersect the contact upon which the main orebody is supposed to be. This is the only high-grade ore found at this depth in the district, and upon the showing, the company has installed a skip in the winze on the 1100-ft. level, increased the working force, and is to open a new level below the 1550.—A number of stockholders of the Scott Hill Mining Co. visited the property between Alta and Park City and have decided to drive an adit 200 ft. below the lowest workings in the mine to prospect the ground and facilitate the handling of the ore. The Scott Hill is the old Copper Apex mine from which considerable ore has been shipped in the past.

TOOELE COUNTY.

The International Smelting & Refining Co. has 600 men at work re-modeling the old Highland Boy smelter, in Pine canyon, and expects to have the plant in commission shortly after the first of the year. Sixteen McDougall furnaces have been erected and the smoke stack, which is to be 340 ft. high, is up 50 ft. The plant will treat custom ores and as a result there has been a revival of interest in the mining industry of the Ophir and Stockton districts.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The hearing of the case of the Old Republic Mining Co. v. The New Republic Co. in the Federal Court, at Spokane, was compromised by the attorneys recently, and it was agreed that the New Republic Co. should work the mine and deposit the net earnings with the Ferry county treasurer pending the hearing of the suit for a permanent injunction. Work has been resumed in the mine, and about 80 men are on the pay-roll.—The Lone Pine lease is now a success, the shoot yielding ore which assays from \$17 to \$300 per ton.—The Ben Hur mine, after a considerable outlay, is paying more than expenses now that it is leased to the Ben Hur Leasing Co., which has discovered rich ore at a depth of 275 ft. This company has obtained an extension of its lease for three years, making in all a five years term. It is also in the market for a new steam-hoist, 80-hp. boiler, and an air-compressor, to run 10 machine-drills, of which 3 are now in commission and 7 more are to be added shortly. The leasing company has planned to sink the shaft to a depth of 625 ft. and open the mine on three more levels. Water sufficient for present use is taken from the mine, but an extra supply will be obtained by piping from Mud lake, about 2000 ft. distant.—The Belcher mine is sending out four carloads of ore per day to the Granby smelter. A new orebody has been found, in which lead is present with the iron.—It is reported that operations will be resumed in a few days in the Copper Key mine, on Belcher mountain, and carried on more extensively than before.—A new body of ore has been found in the No. 36 shaft of the Oversight mine, at a depth of 80 ft. The shaft was sunk 40 ft, through iron carbonate and sulphide and then cut

Philippine Islands.

ning.—The Aroroy Mining Co. has been incorporated to open the Goldbug group formerly owned by Edelmaler & Beasley.—A new hoist has been installed by the Cripple Creek Mining Co. on its Colorado group. T. A. Draper is in charge of the work.

UTAH.

JUAB COUNTY.

After ten years of litigation the Supreme Court rendered a decision in favor of the Grand Central Mining Co. against the Mammoth Mining Co. and the Mammoth company paid \$30,000 of the \$176,385 which the court found against it. While the amount of money involved in the suit was large, the main factor in the case was the ownership of several large orebodies upon which all work had been stopped by injunctions from the courts. It has not been decided whether the money will be paid out as dividends or used for further development work, but should the directors de-

through a bed of limestone before the discovery was made.

—Work has been resumed at the Anonymous mine.

Republic, October 30.

OKANOGAN COUNTY.

The Molson Gold Mining Co., operating the Poland China property, northwest of Chesaw, has called a special meeting of its stockholders for December 13 to vote on an increase in the capital stock to 4,000,000 shares. R. I. Plomert, formerly with the C. M. Fassett Co., of Spokane, is now at the property planning an extensive development and exploration campaign from the shaft on the 100-ft. level.

STEVENS COUNTY.

John A. Wilson, of Spokane, and O. M. Matthews, of Northport, have obtained control of the Paragon property, seven miles east of Northport, and will begin active development at once on two well defined shoots of high-grade ore.

CANADA.

BRITISH COLUMBIA.

An arrangement has been reached between the employees of the former Dominion company and the New Dominion company, whereby the men will receive 75% of the wages due them from the former company, and work has been resumed in the Rawhide mine, though it is probable that the Brooklyn and Idaho properties will be idle for some time. A new crusher will be installed in the plant and the ore crushed before going to the plant of the British Columbia Copper Co.—For the week ending October 27 the Granby company shipped over 27,000 tons of ore to the smelter at Trail. The eight furnaces now have a capacity of 4000 tons per day, and the shipments from the mines can easily supply this, as on the record day 5000 tons were hauled to the plant.—Charles Dempster, of New York, has given up his bond on the Hattie Brown property, as the owners insisted that cash payments be made, and so far as the development had shown, this was not warranted.

ONTARIO.

That the Government was satisfied with the prices obtained at the sale of the Gillies Limit is evinced by the fact that 1188 acres additional, south of the lots previously sold, has been placed on the market. This makes a total of 2100 acres offered for sale by the Government out of 64,000 acres contained in the Limit.—Power from the Ragged Chutes plant was made available for the Colonial and King Edward mills at Cross Lake, and operations have been resumed at both plants. The King Edward has been completely re-modeled.—The Cobalt Twins Silver Mining Co. has installed a diamond-drill and will prospect the vein to considerable depth before any further work is done in the shaft.

MEXICO.

CHIHUAHUA.

The new manager for the Lluvia de Oro Mining Co., H. R. Conklin, has purchased a hydro-electric power plant for installation on the Fuerte river. A dam will be built across the river to secure a 40-ft. head and the plant will transmit power five miles to the mill. The latter was started last month after great difficulties in landing the material at the mine. None of the machinery was sectionalized.

OAXACA.

The old Guadalupe mine, in the Sierra Juarez district, has been re-opened, and in the course of development, sufficient rich ore was found to pay for all current expenses by treatment with an arrastre. This ground is close to the Natividad mine and is being developed by J. L. Grandison and A. Buttner, of Oaxaca.—The option held by Denny Brothers on the San Juan property has expired and the owners, Juan Baight, Jesus Acevedo, and Lic. Cervantes, have refused an extension of time.

TEPIC.

The Zapote Mining Co. has begun the erection of a reduction plant on its property near Eliseo, and expects to have it in operation before the end of this year. The mill will consist of five stamps, a tube-mill and cyanide tanks, and will be operated by water power.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. C. HARDER was in San Francisco this week.

W. C. MENDENHALL has returned from Hawaii.

COREY C. BRAYTON is in South Dakota examining properties.

C. L. CONSTANT, JR., has just returned to New York from Cobalt.

F. K. BORROW has returned from Manchuria and is now in London.

E. A. HOLBROOK, of British Columbia, has been in San Francisco.

O. H. PACKER has gone to Washington, Sierra county, California.

J. M. CALLOW has returned to Salt Lake from the Hawaiian Islands.

GEORGE S. TYLER has returned from Rawhide, Nevada, to Oakland, California.

L. N. B. BULLOCK passed through London on his way from Mexico to West Africa.

R. S. RAINSFORD, who has been recuperating in Scotland, has now returned to California.

D. E. McPHERSON has opened an office in the Hooper Bdg., Salt Lake City, Utah.

H. D. BRUNING and C. B. NIMS, mining and civil engineers, have opened an office at Seattle.

FREDERICK H. MINARD has returned to Denver from an extended trip to Central America.

J. E. SPURR visited the Monte Cristo district, in the Cascade range, Washington, last week.

J. J. BENNETT, of DeLamar, Idaho, has been visiting the Comstock, and is now at Austin, Nevada.

J. R. WOLFE, of Portland, is superintendent of the Grey Eagle mine and mill near Gold Hill, Oregon.

C. W. MERRILL, of San Francisco, was recently at the Nickel Plate mine, Hedley, British Columbia.

ROBERT ALLEN, lately at Parral, Mexico, sailed from London for South Africa on October 16.

FRANCIS W. SEWELL has resigned as metallurgist to the British-Mexican Development Co. of London and Mexico.

JAMES A. BARR, of Seattle, has gone to Silverton, Colorado, to take a position with the Intersection M. & M. Company.

S. F. BRETHERTON has returned from Lodi, Nevada, where he started the lead smelter of the Lodi Mines Company.

J. CLARK, of Bisbee, Arizona, has been appointed general manager for the Mammoth Copper Co. at Kennett, California.

ELMER A. HOLBROOK has resigned as superintendent for the Daly Reduction Co., Ltd., and is at Fitchburg, Massachusetts.

FRED T. WILLIAMS is examining the mines of the Mount Wilson Gold & Silver M. Co., at Newmire, Colorado, for Eastern interests.

HERMAN KELLER, of New York, is to make a professional visit to Los Angeles and other points in the Southwest the latter part of October.

A. S. HASKELL, general manager for the Mammoth Copper Co. at Kennett, has resigned and will hereafter make his home in San Francisco.

ERNEST A. HAGGOTT is at the mines of the Yuma Copper Co., Vicksburg, Arizona. He will examine properties in Pinal county before returning to Los Angeles.

C. R. MORRIS has resigned as superintendent at the Monaldo mine, Masonic, California, to accept a similar position with the Pittsburg-Liberty Mining Company.

F. T. HAVARD has been appointed assistant professor of mining and metallurgy at the University of Wisconsin. Mr. Havard is a graduate of the Royal School of Mines, Freiberg, and has had metallurgical experience in Germany, Chile, Montana, and elsewhere.

Permissible Explosives.

The following list of permissible explosives tested by the United States Geological Survey at Pittsburg, Pa., is hereby published for the benefit of operators, mine owners, mine inspectors, miners, and other interested. The conditions and test requirements described in Explosives Circular No. 1, published in the MINING AND SCIENTIFIC PRESS, June 5, have been followed in all subsequent tests. Subject to the provisions named below, a permissible explosive is defined as an explosive which is in such condition that the chemical and physical tests do not show any unfavorable results; which has passed gas and dust gallery tests No. 1 and 3, as described in circular No. 1; and of which, in test No. 4, 1½ lb. (680 gm.) has been fired into the mixture there described without causing ignition.

| Brand. | Manufacturers. |

| Tunnelite No. 6..... | Do. |
| Tunnelite No. 7..... | Do. |
| Tunnelite No. 8..... | Do. |

*Reported in Explosives Circular No. 1.

Provided: (1) That the explosive is in all respects similar to sample submitted by the manufacturer for test. (2) That No. 6 detonators, preferably No. 6 electric detonators (double strength), are used of not less strength than 1 gm. charge, consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate (or its equivalent), except for the explosive 'Masurite M. L. F.', for which the detonator shall be of not less strength than 1½ gm. charge. (3) That the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner before use. (4) That the amount used in practice does not exceed 1½ lb. (680 gm.), properly tamped.

The above incomplete list includes all the permissible explosives that have passed these tests prior to October 1, 1909. The announcement of the passing of like tests by other explosives will be made public immediately after the completion of the tests.

With a view to the wise use of these explosives it may be well in this connection to point out again certain differences between the permissible explosives as a class and the black powders now so generally used in coal mining, as follows: (a) With equal quantities of each, the flame of the black powder is more than three times as long and has a duration three thousand to more than four thousand times that of one of the permissible explosives; the rate of explosion also is slower. (b) The permissible explosives are

one and one-fourth to one and three-fourths times as strong and are said, if properly used, to do twice the work of black powder in bringing down coal; hence only half the quantity need be used. (c) With 1 lb. of a permissible explosive or 2 lb. of black powder, the quantity of noxious gases given off from a shot averages approximately the same, the quantity from the black powder being less than from some of the permissible explosives and slightly greater than from others. The time elapsing after firing before the miner returns to the working face or fires another shot should not be less for permissible explosives than for black powder.

The use of permissible explosives should be considered as supplemental to and not as a substitute for other safety precautions in mines where gas or inflammable coal dust is present under conditions indicating danger. As stated above, they should be used with strong detonators, and the charge used in practice should not exceed 1½ lb. and in many cases need not exceed 1 pound.

Boston Consolidated Mining Company.

At the recent meeting of the American Institute of Mining Engineers at Salt Lake the Boston Consolidated distributed a pamphlet giving in detail many interesting facts regarding its Bingham mines and Garfield mill. The data in condensed form are presented below.

Area mined, 378.8 acres, covering both sulphide and porphyry mines, which are separate. At the porphyry mine the development includes 101,914 ft. underground workings. The estimated tonnage is 37,439,000 tons of porphyry ore above 1.5% copper content. The present output is obtained by caving methods, but the mine is equipped for steam-shoveling. At the sulphide mine the development consists of 47,536 ft. of underground workings, and the mining method is by square-sets in stopes. The equipment at both mines includes: tramway, four-track gravity tram, Stine drums (air controlled), lowering 12 tons in car; length of tram 2000 ft., elevation overcome 737 ft., gradient 24 to 55%; 3000-ton cylindrical steel receiving bin; total capacity of tramway, 6000 tons per day; steam-shovels, four 90-ton; locomotives, 12; cars, 146; track, six miles narrow-gauge; air-compressors, three electric-driven, 70 drills capacity; rock-drills, 80; usual shops, warehouse, and boarding-houses. Number of employees: sulphide mine, 102; porphyry mine, 427; shops, 19; total, 548.

Mining costs for September: Production, sulphide mine, 7178 (dry) tons of ore, 310,000 lb. copper content; porphyry mine, 71,880 (dry) tons ore.

SULPHIDE MINE (SQUARE-SET METHOD).

| | Cents per ton. |
|-------------------------------|----------------|
| Stopping ore. | |
| Breaking ore | 29.1 |
| Mucking | 35.2 |
| Timbering | 50.1 |
| Electric haulage | 9.6 |
| General expense | 4.1 |
| Sulphide mine expense | 12.0 |
| Cost of mining | \$1.401 |
| Development in waste..... | 0.287 |
| Total cost of production..... | \$1.688 |

PORPHYRY MINE (CAVING METHOD).

| | Cents per ton. |
|---------------------------|----------------|
| Breaking ore | 18.8 |
| Mucking | 16.5 |
| Timbering | 7.7 |
| Electric haulage | 4.0 |
| Gravity tram | 2.5 |
| Mine expense | 5.0 |
| General expense | 2.2 |
| Development expense | 10.0 |
| Total cost | 66.7 |

Garfield mill: mill-site area, 910 acres. Buildings: foun-

dry, steel building 60 by 80 ft.; equipment (motor-driven), No. 3 Whiting cupola, No. 3 brass furnace, No. 4 Root blower, 12,000-lb. jib-crane. Machine shop: frame building, 44 by 178 ft.; equipment (motor-driven), one each of the following: 10-ton traveling crane, 36 by 24 triple engine lathe, 20 by 20 lathe, No. 6 Barnes vertical drill, 24-in. shaper, No. 55 bolt and pipe cutter, power pipe cutter, No. 21 plate shear, 8-ft. Poole boring mill, 18-in. key seater, 5-ft. Niles radial drill, 1100-lb. Bement steam-hammer. Transformer building: concrete and brick, 60 by 72 ft.; equipment, four 1000-kw. 80,000-460 volts Westinghouse transformers, three 250-kw. 460-2300 volts Westinghouse transformers, three 75-kw. 460-115 volts Westinghouse transformers for lighting; one set 80,000-volt choke coils, one set 80,000-volt arresters, one 9-panel distributing switch-board. Power transmission at 40,000 volts. Distance, 144 miles from Telluride Power Co.'s Grace, Idaho, station. Crude-ore bin: steel building, 300 by 36 ft., capacity 12,000 tons. Crusher house: steel building, 66 by 78 ft.; equipment (motor-driven), two No. 6 Gates gyratory crushers, two No. 5 Gates gyratory short-head crushers, screens, and conveyors. Mill: steel building, 326 by 590 ft.; equipment (motor-driven); crushed-ore bin, 21 by 570 ft.; 312 1500-lb. Nissen stamps (duty 114 drops per minute, 6½-in. drop, capacity 8.73 tons per stamp-day), 299 Wilfley tables, 221 Johnston vanners, 312 Callow tanks, classifiers, launders, etc. Flow from stamps by gravity throughout. Tailing and concentrate flow from mill through one central tunnel, having 13 branches beneath mill. Heating plant: frame and iron building; equipment, three 80-hp. boilers. Main pumping plant: brick building, 30 by 50 ft.; equipment (motor-driven), one 3-stage Byron Jackson centrifugal pump, capacity 3000 gal. per minute; two 4-stage wood centrifugal pumps, capacity 1500 gal. per minute. All against static head 380 ft.; 4316 ft. 20-in. wood-pipe line. Concentrate bins (concrete): nine bins, capacity 200 tons each; concentrate loaded by Browning crane into railway cars. Assay office: brick. Store-room: frame, covered with iron.

Men employed: foundry, 15; shops, 21; electrical department, 6; total, 42. Mill: unloading ore, 10; crusher house, 18; mill, 114; loading concentrate, 3; total, 145; clerical force, 5; assay office, 2; other outside labor, 34; total, 41; grand total, 228.

Results for September: received 77,003 tons; milled 72,000 tons (dry); produced 3550 tons (dry) concentrate containing 1,569,000 lb. copper; recovered 21.8 lb. copper per ton crude ore; average head 1.58%; power required, pumping 469,280 kw. hr.; milling 989,265 kw. hr.; possible stamp-hours, 224,630; actual stamp-hours, 214,145; percentage run, 95.3.

MILLING COSTS.

| | Cents per ton. |
|---------------------------|-------------------|
| Crude-ore bin | 1.09 |
| Crushers | 4.49 |
| Stamps | 21.97 |
| Wilfley tables | 2.45 |
| Vanners | 3.35 |
| Launders | 0.51 |
| Callow tanks | 1.01 |
| Loading concentrate | 0.44 |
| Tailing dump | 0.74 |
| Water supply | 7.50 |
| Heating plant | 0.04 |
| Mill expense | 3.41 |
| General expense | 3.11 |
| | 50.11 |

Spring Stamps.

The use of spring stamp-mills in South Africa and India antedated their introduction into the United States by many years. The gravity stamp is so generally used that mill-men have failed to even investigate the claims to consideration of the rapid-drop hammer-stamp. A mill of this type, which the makers claim develops large capacity with small power-consumption, has recently been put in the mar-

ket by the Oakland Stamp Mill Co., Oakland, Cal. It consists of an all-iron and steel frame resting upon a concrete foundation, comprising two independent mills, the stamps being actuated by an eccentric cam-shaft. The face of the blow is increased by properly arranged springs. The stamps weigh 300 lb., and strike 200 blows per minute. The force of the blow is computed to equal that of an 1800-lb. gravity stamp. The first mill built crushed 15 tons of Rawhide, Nevada, ore, containing large quantities of talc and clay, through a 40-mesh screen in 24 hours. The makers have issued an attractive catalogue (No. 1) describing this mill. It also contains other interesting and useful information for mill-men.

Commercial Paragraphs.

W. C. STEWART has purchased and taken charge of an assay office in Portland, Oregon.

GUY H. GIBBS, who has been with the Westinghouse Electric & Manufacturing Co. for the past eight years, four of which have been with that company's Cincinnati office, is now with the Western Electric Co. at Cincinnati.

The SHEFFIELD GAS POWER Co., Kansas City, announces that it has purchased, at bankruptcy sale the entire assets, factory, and good-will of the Weber Gas Engine Co., and that it is now prepared to furnish the Weber gas engines and gas producers.

The ALLIS-CHALMERS Co.'s eighth annual report just issued shows net earnings for the year of \$135,431, after deducting cost of manufacturing and selling, taxes, insurance, other general expenses, dividends on preferred stock of the Bullock Electric Mfg. Co., and provision for doubtful accounts, amounting to \$1,809,009.

At the second annual meeting of the ECONOMIC MACHINERY Co., held last week in its Denver offices, it was decided to enlarge its present plant and erect additional buildings for the manufacture of mining machinery. C. C. Wilson, who is president of this company, after a brief trip to the West, declares in favor of Denver as a manufacturing point for mining equipment. Salt Lake City and a prominent Pacific Coast point will also figure largely in the immediate extension of this company.

BURE & FERGUSON, engineers with offices at the Loo Bdg., Vancouver, British Columbia, are constructing a 20-mile ditch system for the Quesnelle Hydraulic Gold Mining Co., in the Cariboo mining district and are now in the market for supplies needed in the construction of dams, tunnels, ditches, flumes, steel and wooden pipe-lines, mine equipment. They desire that catalogues or literature on such supplies be sent to the above company at Quesnelle Forks, by way of Ashcroft, British Columbia, and a duplicate set to their office at Vancouver.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MINE AND QUARRY. September 1909. Contains an interesting account of the Gunnison tunnel project.

GEOLOGY OF THE MIKONUI SUBDIVISION, NORTH WESTLAND. By Percy Gates Morgan. New Zealand Geol. Surv. Bull. 6, N. S. Pp. 175. Ill., maps. Wellington, 1908.

A monographic account of an area containing important auriferous veins and alluvial deposits.

PRODUCTION OF IRON ORES, PIG-IRON, AND STEEL IN 1908. By E. C. Harder. Advance chapter, Mineral Resources of the United States. U. S. Geol. Surv. Pp. 78. Washington, 1909.

With the statistical report are included two folded maps, showing in colors the distribution of the iron ores and of blast-furnaces in the United States.

GEOLOGY OF THE QUEENSTOWN SUBDIVISION, WESTERN OTAGO. By James Park. New Zealand Geol. Surv., Bull. 7, N. S. Pp. 112, ill., maps. Wellington, 1909.

A welcome discussion of the general and economic geology of an important gold-scheelite deposit.

EDITORIAL.

NOME produced \$3,975,196 this season, approximately a million less than last year. Shortage of water was the principal reason for the decline.

THE COLORADO School of Mines is distributing a convenient little circular on how to recognize pitch-blende. The demand for this mineral is so new that prospectors and others need much education. Fortunately, through the Vinson Walsh Research Department of the Colorado school, the means are at hand for giving the information necessary to a systematic search for this carrier of radium.

INFORMATION from New York affirms the consolidation of the chief copper producers by agreement reached on Thursday. The rumor seems well authenticated, but confirmation is needed concerning the parties to the combination. Those mentioned are the Amalgamated, the various Cole-Ryan concerns, Phelps, Dodge & Company, and probably the Guggenheims. The new combine is said to be closely allied with the United States Steel Corporation, Mr. William E. Corey and Mr. J. Pierpont Morgan being the negotiators. Copper stocks have advanced sharply on account of the rumors, and an excited market will inevitably follow until the facts are officially announced. The details will afford an interesting study in financial equalization of the respective advantages and disadvantages in cost of production of the interests involved. Trading of benefits must be made to effect compromises where producers of low-priced copper consent to furnish a large quota of the metal while producers of expensive copper conserve their ore supplies. Delicate problems are to be solved. The fact of such a combination having been effected seems assured. Its significance to the public is that higher prices will prevail, quotations will be made far enough ahead to insure against an erratic market, and the improvement in price and in the tone of the market will work to the advantage of the smaller independent miners and smelters.

CHESTERTON said that nobody could tell what Mr. Asquith might do next; that like as not Mr. Asquith would presently be seen standing on his head. But the British Premier landed squarely on his feet Thursday week, with a government majority of such strength supporting the budget that only some exceedingly ridiculous experiments as a political cephalopod can now weaken his leadership. The vote of 379 to 149 has so impressed the Lords that a faint gurgle has been heard from the Unionist press indicating submission. The new taxes will go hard with the peers in some respects; they will fall

heavily upon the country as a whole; and the protests against some of the socialistic measures which are absorbing immense sums are not unwarranted. With these questions of internal British politics we have nothing to do, but it is of interest to note that the determination to sustain the Government's plans involves a magnificent campaign of ship-building—if not two for every German battleship, at any rate a naval program so vast that it insures a demand for steel and copper that will be an important factor in trade revival.

WE NOTE with pleasure that the Institution of Mining and Metallurgy, London, has awarded its gold medal to Mr. William Gowland, who has just vacated the chair of metallurgy in the Royal School of Mines. The award is made "in recognition of his services in the advancement of metallurgical science during a long and distinguished career." We hope that career may be further lengthened to good purpose, for, while the Government places an arbitrary limit of age upon the retention of the appointment as professor, it is apparent that nature is more generous to this distinguished exponent of metallurgy.

Alaska and the Geological Survey.

The Director of the Geological Survey has estimated that for the year 1910, an additional appropriation of \$10,000, making a total of \$100,000 for the year, will be needed for the surveys in Alaska. Since the beginning of geological survey work in this territory in 1898, \$721,189 has heretofore been appropriated. With this money something over 17 per cent of the area has been covered by geologic, and approximately 21 per cent by topographic, reconnaissance surveys. In addition, up to the close of last year, 2304 square miles had been geologically surveyed in detail, and 2732 were covered by detailed topographic maps. During the present season 14 parties were in the field.

In addition to the areal surveys noted, a large amount of time and attention has been devoted to collection of mineral statistics, study of water resources, and, particularly, to special investigations of mineral deposits. Of the value of this work no argument is needed. It is interesting none the less to recall that in contrast with the three-quarters of a million dollars devoted by the Government to the study of the mineral resources of Alaska, a total of nearly \$150,000,000 mineral output has been realized. The gold output alone has increased in round numbers one hundred fold from 1880 to 1908, or from \$20,000 to \$20,000,000. That a part, at least, of this great increase is to be credited to the activities of the Survey is beyond question, and it is not to be doubted that the more rapidly and completely the territory is surveyed and studied the more promptly and economically will its great resources become available. At the present rate of progress it would be fifty years before the whole area could be covered by even preliminary maps, and, neglecting areas of little importance, there are at least 200,000 square miles which should be promptly investigated. Laws are now being enacted, railways built, and conditions established, which must control the industrial

development of the country for many years, if not for all time. Sound business sense dictates that the fullest information be made available as promptly as possible, if mistakes are to be avoided.

The high character of the work of the Geological Survey in Alaska is well known. We have taken frequent pleasure in commending it as an excellent example of wise administration, of nice adaptation of means to end. Taking into account funds available, the surveys have been detailed where most needed, and not too expensive where less detail was warranted. The high character of the men employed and their devotion to the work warrants the belief that the larger appropriation which conditions demand will be wisely spent, and Congress should not hesitate to authorize the larger expenditure.

The State Mineralogist Again.

A short time ago we received from the California State Mining Bureau figures of the mineral production of California for 1908 other than gold and silver. We did not publish them, as they were evidently inaccurate, and for most of the minerals better figures were already available in the advance chapters of the Mineral Resources for 1908, published by the United States Geological Survey. For example, the total value of the brick output as determined by the State Bureau was \$2,506,495; the figures given by the United States Survey are \$4,436,619. The corresponding totals for a few other items as determined by the two organizations (the State figures in each case being given first) are: pottery clay, \$325,147, \$87,126; mineral water, \$560,507, \$499,872; petroleum, \$26,566,181, \$23,433,502; pyrite, \$610,335, \$131,744; salt, \$281,469, \$374,828; glass sand, \$22,045, \$5121. After making all proper allowance for differences in classification, it is clear that one set of figures must be radically wrong. Anyone familiar with the men and methods employed by the two bureaus will not hesitate to pin his faith to the Government figures. Any hesitation to do so would be dispelled by a closer study of the local statistics. The State Bureau gives the borax production at 22,200 tons valued at \$117,000. As a matter of fact, the California production in 1908 was worth over \$900,000. Apparently the State Mineralogist is still estimating the product as though it came from the marshes. Instead it comes from mines in Inyo and Los Angeles counties, which yield colemanite containing 35 to 40 per cent of anhydrous boric acid. Valuing the natural gas at 56 cents per cubic foot is evidently a typographical error, but the value assigned to the magnesite (\$7.63) may be seriously criticised. The price is too high for crude and too low for calcined. Our main interest, however, centered in a pathetic little note to the effect that "the statistical returns relating to the precious metals, which are collected by the United States Geological Survey, were not ready for print at the date of the preliminary announcement." This interest has been revived by a second circular just received, in which the United States Geological Survey is taken to task for its failure to provide figures for the local Bureau to

publish. "Incompetency or carelessness" are hinted. If indeed there be incompetency, and as to that we are prepared cordially to agree with the State Mineralogist, all familiar with the local situation will know that the charge should be placed against the State Mineralogist rather than the Government officials. As a matter of fact, however, why should Mr. Lindgren, Mr. Parker, and the other Survey officials furnish statistics for the State Bureau to publish? If it is the function of the latter to publish the figures, it is equally its duty to collect them. All that is necessary is to get men competent to the task; men who have the confidence of the producers.

A Waterways Fund.

For several years increasing interest has been manifested regarding inland waterways; an interest which Mr. Roosevelt's theatrical trip down the Mississippi river did much to awaken, and which Mr. Taft's even more elaborate 'junket' has strengthened. There is, and has been, much unthinking enthusiasm and glib talk without limit. Only a superficial observer, however, dismisses the matter with this. Beyond question there is a deep and well founded conviction among the people that, cost what it may, the waterways must be improved and rendered available for real navigation; that it is worth the price. A scarcely less firm purpose that the work shall be done honestly and with as little as may be of waste, is also evident. The failure of past efforts to control the rivers can be properly ascribed only in part to lack of experience and knowledge on the part of the engineers in charge, a lack which is no discredit, since the problem in its size and variety is new. Mainly the failure is due to the unsystematic manner in which funds have been made available, to the higher costs of Government work, and to the contract system with its trail of political favorites. If the time is ripe to do away with these things, the time is also ripe for improving the rivers. If not, they had better wait. At least that is, as we interpret it, the attitude of the people.

Mr. Francis G. Newlands, the remarkably useful Senator who represents the whole West, though elected from Nevada, recently has come forward with a proposition for the creation of a general Waterways Fund to be devoted to this work much as the Reclamation Fund is used in irrigating arid land. Mr. Newlands emphasizes the point that the Western Senators and Members of Congress hold the balance of power, that they have superior knowledge of certain of the related problems, that the problem of the waterways if solved correctly involves the solution of the most vexatious of the secondary problems of water-storage and water-power, and, finally, that it was Western men who shaped the legislation which gave us the Reclamation Service, "the first piece of constructive legislation in the history of the country that was free from the evils of the spoils system." He does not suggest the source from which the required fifty million dollars a year is to come, but in the light of general discussion of the subject it is evident that bonds must be issued and that rentals of water-power sites are relied upon for at least a large part of the interest and contribution

to sinking fund. American States and smaller units of government have suffered frequently and severely through the issue of bonds for public improvements, and there is a general distrust of the wisdom of a large bond issue for river improvement in particular. Less objection lies against a bond issue to supplement the Reclamation Fund, or a bond issue secured by the water-power sites. In the latter case bonds are inevitable in any event. It is merely a question whether they shall be bonds of private companies with watered stock for a premium, or Government bonds, with, at worst, higher cost for installation and operation.

At Chicago in 1908 Mr. Taft pointed out that there is no objection to bonds in themselves, if the work paid for by issuing them is necessary and is well done. On the other hand, Mr. Cannon has consistently opposed bond issues; the characteristic attitude of the hard-headed country financier. No doubt 'Uncle Joe' by his opposition has, from time to time, prevented much useless as well as useful expenditure, but when, as in his recent Cairo speech, he lauds the present 'contract system' which is synonymous with the 'pork barrel' method, and hints that present revenues will "pay for the plant," we are reminded of the strings of Government dredges and boats rotting at the wharf opposite Chester, Illinois, and other points—plant paid for, manufacturers' profit realized, some single contract perhaps completed, and then the funds cut off. It is just this uncertainty as to the continuous and economical utilization of the plant, that the people wish to avoid. There are times when the public needs deliverance from its friends, and much interest, incidentally, attaches to the story that 'Uncle Joe' has been told that he can not again be elected Speaker of the House unless Mr. Taft can be persuaded to give him a friendly boost, as he did Mr. Tawney and Mr. Aldrich. No more pork barrel legislation is wanted—it were better that the rivers continue to expend their energy in carrying soil rather than commerce to the sea.

The very confusion surrounding the subject of where to begin indicates that no adequate general plan has yet been formulated. At best specifications are only available for individual parts of the work, and the relative importance of these is undetermined. What is now needed is an adequate study by a competent commission, neither a Congressional Committee nor a board of Army Engineers. The problem demands the services of the best men both here and abroad. They should be given time and funds to study the problem as a whole, but, as a guarantee that this is not merely to serve to postpone and defeat the work, a fund such as Mr. Newlands suggests, should be built up and made available for immediate construction whenever the Commission finds any part of the work which it can recommend. If, for example, the present plans for improvement of the Ohio be approved, let work be pushed as rapidly as is consistent with good results. To order that particular work without further consideration seems inadvisable in view of the fact that no provision now exists for utilization of the possible water-power. The American people have no objection to spending money, but they want to be sure of results.

THE MIAMI-INSPIRATION ORE-ZONE.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. TOLMAN, JR.

The Globe region in Arizona has not been dominated by any single great company or group of companies to the extent seen in the other important camps of the Territory. Here the prospector has not been driven out, but has remained as mine-owner, and in cases he has developed his properties with success. The district presents a variety of mineral deposits unusual in Arizona. Globe was at first a silver camp with some gold production from placers, then copper deposits of ordinary type, in limestone, took precedence, to be overshadowed later by a new type of deposit (disseminations) in a formation which had been condemned by prospectors and engineers alike. These mineral discoveries have come as a series of unexpected surprises.^{*} The geological structure presents a patchwork of faulted formations that must have proved a Chinese puzzle of absorbing interest to F. L. Ransome, whose map is a triumph of geologic art. The period of the small silver 'chlorider' began with the first discoveries about 1874, and continued up to 1884. His business was to prospect and mine a part of the time, and to watch for Apaches all of the time. The years 1884 to 1898 saw the development of the Old Dominion and the rise of copper mining, which rapidly became the chief industry of the place. The year 1898 marked the advent of the railroad into Globe, and from that time until 1907, the Old Dominion was considered the big property of the district with the great future, and the Globe hills were supposed to be the premier mineral area of the region, but 1907-1909 has seen the discovery of disseminated sulphide deposits and the opening of a new productive zone, destined to take precedence over the older Globe hill area.

Geology.—According to Mr. Ransome the formations and their sequence are as follows: The Pinal schist, the oldest formation of pre-Cambrian age, containing masses of pre-Cambrian intrusive granites; the Paleozoics, represented by 1000 ft. of maximum thickness of conglomerates, quartzites, and shales of Cambrian age, overlaid by 800 ft. maximum thickness of Devonian and Carboniferous limestones; diabase intrusion, an irregular later intrusion, placed in the Mesozoic by Mr. Ransome, in the forms of dikes, sills, and lenticular masses; Tertiary and Quaternary cover, resting unconformably on all the formations enumerated above, in the form of lava-flows, terrestrial conglomerates, and others, which is but the outer edge of a more extensive series developed northwest of the area.

The absence of the post-Paleozoic granitic intrusion, which occurs in connection with the copper deposits of the other camps of Arizona will be noticed. Observation and theory alike call for an acid intrusion to furnish the copper waters. Nowhere in Arizona do basic rocks, such as olivine diabase, develop contact-zones suggesting the presence of such waters. The copper deposits of the Pacific Coast which Waldemar Lindgren thinks are related genetically to

basic greenstone flows, differ in many respects from the deposits in southeastern Arizona, and furnish no proof that basic rocks can generate a copper depositing circulation in adjacent formations. The opening of the Miami deposits brought Walter Harvey Weed into the district, and his detailed work (which I give from his oral statements), convinces him that the Schultze granite is post-Paleozoic (Tertiary?), and intrusive in the schist. This explains the Miami-Inspiration deposits as lying along the granite-schist contact, but do the orebodies of the Globe hills still remain 'a law unto themselves'?

The Globe hill quartzites, limestones, and diabase are broken into strips by major, and often ore-bearing, northeast fissures. These strips are cut into blocks by a more irregular northwest faulting. The ore deposits are either veins, along the fissures, especially in the diabase, or are spread out from the fissures as replacement-bodies in the limestone. This much is certain, the deposits are connected with fissures. Do these fissures lead into a deeper mass of diabase, or is there any evidence that the Schultze

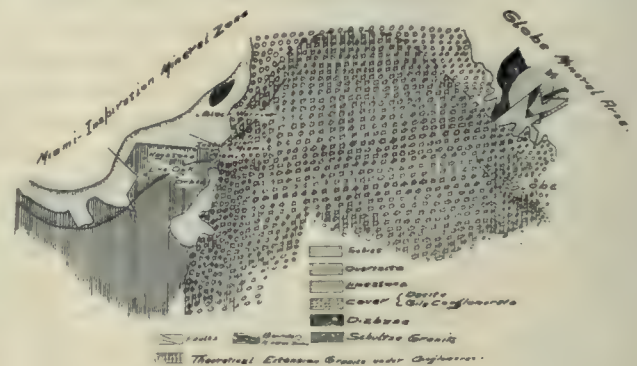

Fig. 1.
Geology of Miami-Globe Region. (After Ransome.)

granite underlies at moderate depth, and was the source of the mineralizing waters, as it undoubtedly was in the neighboring Miami-Inspiration zone. As has been shown in the descriptions of Bisbee and Morenci-Metcalf, and as suggested for the Ray region, there is reason to believe that the intrusive masses spread far out underneath the older intruded rocks, and that the ore deposits are formed at favorable places near the upper contact, where there was an escape for the copper-bearing vapors, distilled from large masses of the underlying acid-rock. A glance at Fig. 1 will show that the Schultze granite is found six miles to the west of the Globe hills bordering the Miami-Inspiration ore-zone, and disappears under a covering of Gila conglomerate, which extends up to a fault southwest of the Old Dominion shaft-house. This fault bounds the orebodies of the Old Dominion on this side. A trip across this conglomerate on foot showed that the boulders are largely of Schultze granite, and along the fault mentioned a deposit of boulders is exposed, with no assorted fine material, the boulders reaching a maximum size of 4 ft. diam., and resembling a brecciated mass of granite in place, rather than a detrital conglomerate. It is inconceivable that these masses of granite could have undergone long water-transportation, and it seems at least reasonable to suppose that they are the result of the disintegration of a nearby mass of Schultze granite, later completely covered with the

detrital conglomerate, and that the mineralization of the Old Dominion fault-zone is due to this same intrusive. This hypothetical extension of the granite is shown in Fig. 1, which otherwise is a simplified sketch from Mr. Ransome's map.

The Miami-Inspiration Ore-Zone.—This mineral zone extends along the contact of the Schultze granite with the schist from the Black Warrior on the northeast through the Miami and Inspiration properties where the schist is the ore-bearing formation, and on through the Keystone and Live Oak where the ore extends into the granite near the contact. (See Fig. 1.) In brief, the zone may be defined as an

Joe Bush shaft of the Inspiration company southeasterly through the Miami ground. The surface of this breccia and the adjacent schist is stained blue with copper silicate and some carbonate. This is the surface outcrop of the 'silicate' ore that can be followed down through the workings. (See Fig. 2.) A fault, difficult to recognize on the surface, but showing excellent slickensides, and gouge underground, separates the schist from the Gila conglomerate. Between this main Gila conglomerate fault and the orebody the schist is shattered, leached, and full of slips. The orebody as now developed lies between these two important structural features, namely, the Joe

Fig. 2.

iron-stained, more occasionally copper-stained, area of schist extending from the Black Warrior to the Needle mountains, the zone extending in places beyond the contact into the granite. For a long time this was thought to be a worthless surface-stained area, but the opening of the Bingham and the Ely deposits suggested the possibility of disseminated deposits under the leached schist near the carbonate and silicate outcrops. J. Parke Channing was favorably impressed with the district, and decided to test the Miami. Within about two years the company has driven some 30,000 ft. of workings, opening ready for stoping somewhere between 10 and 14 million tons of ore from which it is expected that there will be recovered between 500,000,000 and 600,000,000 lb. of copper.

The Miami Orebody.—A silicified fault breccia is easily identified on the surface, extending past the

Bush silicified breccia, and the fractured zone parallel to the Gila conglomerate. The dike of Schultze granite porphyry is uniformly mineralized, having the same assay value as the schist, and structurally has had no modifying effect on the chalcocitization. The plans of the main levels (Fig. 2), which are only rough, idealized, notebook sketches, show how the orebody starts from a point as an apex, about 200 ft. below the surface. The first shaft was sunk on one side of this apex, and it is reported that not striking ore at the expected depth, serious thoughts of abandoning the property were entertained. Had this been done it is probable that the copper of this great ore-zone would have been saved, perhaps, for future generations, for all the subsequent developments in this region have been done on the strength of the work of the pioneer company. The shell of silicate ore partly surrounds the chal-

cocite dissemination, carrying 2% and more of copper, and is of possible use as silicious convertor-lining, or, perhaps, as leaching ore. Leached country rock extends the rest of the way around. The silicified shell forms a rather impervious bar that resists the descending enriching solutions, and has been an important feature in guiding the development of the chalcocite deposit, while the open country along the Gila conglomerate carried down the ore in that direction to the unusual depth as shown in this mine.

On the first main level (270 ft.), one acre of ore has been developed with an average value of 3.19% copper. The next (370-ft. level), shows 11½ acres developed at present averaging 2.96% copper. On the 470-ft. level there has been developed already 16 acres, assaying 2.75% copper, and on the 570-ft. level the boundaries of the ore have not been reached,

copper-stain, and when in contact with limestone develop garnet-contact zones. When these intrusions are a normal fine-grained porphyry, as for instance the Sacramento stock of Bisbee, or when they are in contact with, or cut Paleozoic strata, there is little danger of confusing them with the old pre-Cambrian inert granite intrusions. Identification of the mineralizing intrusions is more difficult when they are granitic instead of fine-grained porphyritic. The following criteria for the separation of the two classes of intrusives are applicable only in the southeastern Arizona region, and are provisionally offered. The pre-Cambrian granites are even grained. They do not develop extensive porphyritic facies near contacts and in peripheral dikes. The occasional development of the gneissoid and schistose structure is peculiar to the older granites. Stratification of the granite with schists and gneisses indicates pre-Cam-

Fig. 3. Plan.

All levels and sub-levels (25 feet apart) are laid out according to this plan. At A and B the top slicing is started, the arrows showing the direction of retreat.

Plan showing system of extraction drifts in each level and sub-level, with alternate pillar and room, and raises.

the average value of the material driven through being 2.65% copper. The top shell of the chalcocite orebody carries the highest metallic content, in places reaching 5%, but soon dropping to the average below.

Genesis of the Ore.—As far as I am aware the original unenriched ore has not been found in the Miami, as yet. The schist area to the southwest, however, contains disseminated chalcopyrite, probably primary ore, and the Gibson deposits are high-grade narrow chalcopyrite veins. This suggests the probability of chalcopyrite and copper-bearing pyrite as the original ore developed by the intrusion of the Schultze granite, the faulting starting soon after the intrusion, and continuing up to recent times, silicification starting in the fault breccias, and spreading into the schist. The commercial ore is, of course, a secondard sulphide deposit, a concentration by descending waters of metal leached from above.

Summary of Geology.—In southeastern Arizona the copper orebodies are found in the vicinity of copper-bearing post-Carboniferous granitic porphyry intrusions. Such intrusions often contain considerable

brian age. The muscovite granites, as far as I have observed them, are all pre-Cambrian.

The post-Carboniferous granites are always porphyritic. Even where holocrystalline, large feldspars occur the Schultze granite and the Ray granite contains feldspar crystals up to even four and five inches in length. The Helvetia granite shows crystals nearly as long. Along dikes and contacts fine-grained porphyry facies occur, often very silicious. The outcropping schist above the copper disseminations shows areas that have suffered considerable silicification. This is more noticeable at Ray than at Miami. Studies are now being carried on to determine what portion of the silicification accompanied the primary mineralization, and what, if any, is caused by descending alkaline waters, with the copper in solution as bicarbonate and silicate, as has been suggested in a previous paper. On the Miami ground fine specks of iron in the schist lie over the ore, and are the residuum left by the oxidation of the disseminated pyrite and chalcocite. This is the most important criterion indicating the deposits below. At the Ray the leaching has gone further, but even there residual

iron specks can be detected in the bleached white schist. Copper salts (carbonate and silicate) are invariably alongside or over a portion of the orebody. They represent the indurated portion of the cap that has resisted leaching, and the best bodies can be expected under the softer, more leached rock, adjacent to the stained area. Finally the structural features govern the descending copper-bearing waters, and, therefore, determine the position of the orebody. At the Miami, the orebody opened to date has been found to lie between two fault-zones. At the Cactus properties, it has been reported that the upper surface of the diabase intrusion has been the guiding

Fig. 5.

Cross-section through series of pillars and rooms.

feature, the latter in this case being impervious to the descending waters, turning them back into the schist, and the highest metallic content is found along this contact. At Ray the main structural feature is the Pinal creek fault, the ore-mantle dipping and extending to this fault, and as should be expected from

Fig. 6.

Cross-section through pillars and rooms. A. cross-drifts being driven toward pillars. B. broken ore.

this structure, recent developments are showing that the ore-stratum has excellent metallic content under Pinal creek up to the fault. The wide red iron-stained belt along the contact of the granite with the schist marks the general extent of the Miami-Inspiration mineral zone, and the portion of this extensive area that is underlain by economic deposits is now being determined by active development along the belt.

Mining Methods.—The system of blocking out this great orebody, and the plans for mining it, developed by N. O. Lawton, the superintendent of the Miami Copper Co., show a number of novel features, and although the stoping operations have not yet

been started, it will be of great interest to know, later on, how far, if at all, these ingenious plans will have to be modified as mining operations proceed. As the short time at my disposal during my visit at the mine, precluded close study of the operations, I submitted my sketch of the methods to Mr. Lawton, who has kindly reviewed them, making a number of corrections that have added to the accuracy and clearness of the descriptions. Two methods are planned, the ordinary Lake Superior top-slicing method, and a room and pillar method, with attack of the rooms by sub-levels from the pillars, named by Mr. Lawton "the auxiliary raise and sub-level stoping method."

The mine is laid out in multiples of 50 ft., and all the workings are numbered by a co-ordinate system, the north and south drifts being 50 ft. apart, and the east and west drifts 50 and 100 ft. apart. All levels and sub-levels are directly above one another and are practically duplicates in so far as the size of the orebody on the different levels permits. Raises are put

Fig. 7.

Plan of haulage roads. (After Herrlek, *Mines and Minerals*.)

up to the capping every 50 ft. along both the north-south and the east-west drifts. They are placed in the corner of the blocks, at one side of the drifts, giving clear passage-room on all the sub-levels, and preventing as much as possible certain 'unlucky' miners from exercising their penchant for stepping down chutes. Sub-levels are opened from the raises every 25 ft. in height, and drifts are run connecting the raises as noted above. With the mine blocked out in this way, any system of sub-level mining can be used, and may be changed from one to another as necessity may arise during operations.

In the top-slicing system attack is started by driving cross-cuts into the centre of each block, on either side of a raise, these cross-cuts meeting similar workings from the drifts as shown in Fig. 3. The driving of this cross-cut takes a slice about 6 ft. high, and retreating along the same drift, the overhanging ore is taken down by upper shots as well as an extra slice along the side of about 4 ft. by side-shots. The distance between slices is $12\frac{1}{2}$ ft., so that less than half is taken out on the advance, and the rest on the retreat. After the ore has been removed the

overburden is made to cave in small sections by pulling the timbers. This driving and retreating is repeated, working back toward the raise. In the combined methods, a room and pillar together will have a width of 100 ft., and run across the orebody, Fig. 4. The extraction drifts and raises having been driven as described above, the only modification is that in the block that is to be mined as a room, the raises will be branched between the first sub-level and the extraction level, as shown in Fig. 5, while in the pillars they will be vertical as elsewhere in the mine, and be used as manways. Mining will begin 50 ft. above the first extraction or tramming level, where the room is cut out the full size of the pillar, 8 ft. high, and then a cut is blasted off the roof, making the height of the room about 14 ft. Operations are transferred to the next sub-level above. Cross-drifts are run from the main drifts beginning in the centre of the room, each cross-drift meeting a similar working from the next main drift, just as was done in the top-slicing method. (See Fig. 5 and 6.) The order of this cross-cutting, or side-stoping, is 1, 2, 3, as shown in Fig. 5, the retreat, of course, being toward the pillar. When driving each cross-drift, not much over 6 ft. of ore is broken, but on the retreat long holes are driven in the roof and in the floor and on the side toward the pillar, the ore being broken through to the room below, half way up to the sub-level above, and an extra slice is taken off of the side. Operations are then transferred to the next sub-level above, and before blasting each slice, sufficient broken ore below is drawn off to make room for the addition. The novel feature is that this method permits of the men always working in solid ore on all the sub-levels, and allows large cuts or ore burdens on the long machine holes, with resultant economy. On reaching the top, the mat is laid, and if the pillars and roof do not stand well enough to permit drawing the ore during the operations, the roof is caved and the fill is drawn off. The plan is then to remove these pillars by top-slicing, but any other of the many possible ways to attack them can be adopted. It appears to me, that theoretically the best method would be to weaken the pillars sufficiently by stoping so that the drawing of the rooms would take down the entire orebody, pillars and all, or a large section of it. Probably enough consideration has not been given, in the development of caving methods, to the advantages of drawing down evenly large areas of ore, thereby obtaining the minimum mixing of ore and cap, and the maximum self-grinding action during the drawing. Mr. Lawton comments as follows on this new 'auxiliary raise and sub-level stoping method' described above. "I estimate that over 50% of the ore can be removed from rooms very cheaply by this method, recovering a high percentage of the ore, and keeping the same clear from mixtures of rock. After the rooms have been mined by this method, the pillars will be taken by the 'top-slicing method', or 'sub-level caving method' (the word 'caving' as here used applies to the cap-rock, or over-burden, allowing the same to cave as the ore is removed, and does not apply to the ore, as none is to be mined by caving it). In a general way, the 'auxiliary raise and sub-level

stopping method' is similar to the 'back-stopping method', but instead of the men working in the open room, and standing on the broken ore while stoping, as necessary in the 'back-stopping method', they work from the pillar or solid ground; in other words it consists in stoping and mining the ore by means of auxiliary raises and sub-levels, namely, after cutting out the room the proper width and length at the level where mining is to begin, a cut is then blasted from the back, which will make the room about 14 ft. high. Thereafter the drilling and blasting is done from the sub-levels. Side holes, uppers, and down holes are drilled from the sub-levels, working from the centre of the room back toward the pillar. The men are thus always working in the solid ground, and use the raises in the pillars for going to and from their place of work. In some cases the ore can be drawn from the rooms as fast as broken until the capping is reached; in other cases it will be necessary to leave the room full to keep the pillars intact or from sloughing. After the room has been mined, and the ore drawn off, it will be allowed or made to fill with cap-rock, and the pillars are then removed by slicing from the top. These slices at the Miami will be 12½ feet. The tramming system is also peculiar to the Miami. It is a rectangular system, with a rectangle in the centre and lateral drifts running out from three sides to the extremities of the orebody. The system allows the drifts to be laid out directly under the levels above, with only 'one way turn-off' at any point, and all the switch-points running with the loads toward the shaft. (Fig. 7.) Tramming levels are placed 50 ft. below the levels on which the mining is to begin, and a series of raises with inclined branches are run up to the bottom of the rooms by which the ore will be drawn into the cars and thence trammed to the shaft. The important points claimed for the 'auxiliary raise and sub-level open-stope method' in connection with the 'sub-level caving method', are: a large percentage of recovery, a clean product, cheap mining, safety for the men, and exceptional facilities for watching the operation of the stopes; also the elasticity of all development work for this method, it being such that we can grade from the 'auxiliary raise and open-stope method' to the 'top-slicing method' or the 'top-slicing caving method' as desired, or as may become necessary in the process of mining." Mr. Lawton states that the blocking of the ore ready for mining, has cost from 12 to 14c. per ton, and the total mining cost is conservatively estimated about \$1.25 per ton, although it is confidently expected to produce it for less than \$1 per ton.

Tin ore is not usually accompanied by manganiferous minerals. The characteristic associates of cassiterite are fluorite, topaz, tourmaline, and spodumene; that is, minerals containing fluorine, boron, and lithium. But tin oxide is undoubtedly dissolved by alkaline waters, and re-arrangement of the tin-content in the original lodes is often produced as a result of the alkaline waters formed in the decomposition of the feldspars; so that it is quite conceivable that cases should arise where subsequent vein-filling had resulted in bringing manganese in considerable quantity into association with tin.

CONTINUOUS COLLECTION OF SAND FOR CYANIDING.

By W. A. CALDECOTT.

*Given adequate plant, a total residue of only one-third of a pennyweight of fine gold per ton of ore, equivalent to 93% extraction on 4.8 dwt. ore or 96% or 8.3 dwt. ore, is usually obtainable with profit on the Rand.

The capital expenditure on plant still remains absolutely high for a huge modern plant handling several thousand tons of ore daily. As regards the secondary treatment, I was authorized in the beginning of 1907 to endeavor to effect some saving in the cost of the usual cyanide plant. It appeared that the most likely prospect of success lay in eliminating the sand-collecting vats, or rather in utilizing them for treatment purposes instead of merely as sand-storages, which take the place of the old tailing-dams. The upper vats of the superimposed type of sand plant were, on their first introduction before the war, utilized as treatment-vats as well as sand-collectors, but the results of contamination of mill-water with cyanide caused this practice to fall into disuse, and in any case a considerable time elapsed between the filling of a vat and its charge yielding gold-bearing solution to the boxes. Hence, although it reduced cost of transfer to a minimum, this type of plant fell into disuse as being expensive, and having only one-half its capacity available for extraction purposes, and was replaced with separate blocks of collectors and leachers (with belt or truck transfer) in the ratio of 1 to 2 or 2 to 5, which is now the common practice.

The use of conical classifiers appeared the most ready means of removing the great bulk of the slime and water, and in the early part of 1907 I tried at the Knights Deep-Simmer East joint plant various combinations of such classifiers with other devices for removing the surplus moisture from the thick sand-pulp underflow of the classifiers. The ordinary type of slime-filter with vertical filter-leaves was obviously inapplicable, and a continuous action was desirable, while the question of washing the sand-cake on the filter did not arise at this stage. A practicable centrifugal separator with continuous discharge was not known to exist, and finally a horizontal type of vacuum-filter appeared the most feasible device. The first filter constructed on this principle was a horizontal launder with false filter-cloth bottom, below which a vacuum was maintained. The sand-pulp was continuously fed into the filter-launder at one end and scraped slowly forward by a belt scraper-conveyor to the other. But a certain measure of success was thus attained, the continuous movement and disturbance of the layer of sand-pulp undergoing filtration prevented efficient removal of moisture, and the trial of another filter of the same type but with a worm scraper-conveyor yielded no better results. Finally there was installed a slowly rotating horizontal filter, which proved so satisfactory that little modification in its design, except increase in dimensions and varia-

tion in details of driving mechanism, has since been made. This sand-filter was 10 ft. in external diameter and consisted of an annular launder 12 in. wide containing a filter-cloth as a false-bottom. The filtering area was thus 28.3 sq. ft. The space under the filter-cloth was connected by means of radial pipes to a central hollow spindle, in which a vacuum was maintained from a receiver. To the lower portion of the receiver was connected a water-pump and to the upper a vacuum air-pump. This filter gave such promising results, by handling sand in unwashed sand-pulp at the rate of up to 200 tons per day, that another, 15 ft. in external diameter and with 18 in. filtering breadth was constructed at the Knights Deep. Among other results over 1600 tons of sand were collected by this filter and transferred by belt to the leaching vats, and when treated yielded somewhat better extraction than usual.

At the present time the underflow of the primary cones at the Simmer & Jack, being too low to gravitate upon the table, is mixed with slimy water from the tailing pulp to form a fluid pulp and pumped into a secondary cone, placed above the table and delivering upon it a thick flow of pulp containing about 30% of moisture. To ensure a thick steady underflow of pulp in large amount a disc, which I have termed a diaphragm, is placed near the bottom of the cones, which are run nearly filled with settled sand. This device has been adapted for tube-milling classification. The sand from which the surplus moisture is removed during the almost complete circuit of the filter, is continuously scraped off by a fixed incline plow some three feet behind the point of onflow. It falls into a hopper where it mixes with a stream of cyanide solution and is pumped to the distributor of the collecting and treatment vat, which the solution overflows to a solution-storage and is returned by a pump to the hopper, thus completing the circuit. In this way the transfer of the sand from the filter to the vat is effected as a pulp, and an excellent start of the dissolving operation is made by the agitation and aeration the sand undergoes in the pump, and during its travel along the delivery pipe or launder to the collecting vat. The system of solution-transfer has the advantage of great flexibility and relatively small cost of installation, while the operating cost is mainly that of power and maintenance of centrifugal pump liners and propellers. The dissolving of the gold in the sand hence begins on falling into the hopper, within half an hour after the ore is crushed, and by the time the vat is filled and drained half the gold in the sand is dissolved.

An important feature of the Simmer & Jack trials was the determination of the relative extraction yielded by completing the treatment of the sand in the vat where collected, as compared with the result of transferring the charge by truck after first treatment to another vat, but the final result was much the same; yet the transfer, and consequent aeration of the particles while moistened with cyanide solution, ensured a quicker dissolution of gold, so that while six days actual treatment sufficed with transfer, nine days was required to complete the single-vat treatment.

The 15-ft. table has been in regular use from the

*Abstract of paper read before the Chemical, Metallurgical & Mining Society of South Africa.

end of last year and has handled up to 10,000 tons of sand per month. The following comparative results are averages from January to July, inclusive of ordinary and continuously collected sand:

| | Continuous collecting. | Ordinary system. |
|---|---------------------------|---------------------|
| Tons of sand treated monthly..... | 7,937 | 37,009 |
| Grading analysis— | | |
| + 60 (0.010 in.)..... | 12.9% | 10.9% |
| — 60 + 90 | 32.7% | 24.1% |
| — 90 (0.006 in.)..... | 54.4% | 65.0% |
| Ratio of solution to sand applied as washers to charge..... | 1.54 to 1 | 2.02 to 1 |
| Number of days treatment in sec- ond vat after truck transfer..... | 4.09 | 6.50 |
| Percentage extraction | 82.878 | 81.594 |

It will be observed that owing to the more perfect elimination of slime the sand filter product is coarser and richer than the ordinary sand, and that the solution precipitated and the time of treatment in the secondary vats are much less with filter-table sand than ordinary sand.

Early in the present year two 20-ft. diam. sand-filters, each with filtering launder 30 in. wide and 137.5 sq. ft. in area, were installed at the Simmer Deep-Jupiter joint plant, and after some preliminary runs have handled all the sand produced during the last five months, up to 2600 tons of ore being milled at times per 24 working hours. The capacity per square foot of filtering area of the Simmer Deep sand-filters is about 50% greater than that of the Simmer & Jack filter, owing to the slime being so thoroughly washed out that less than 1% remains in the collected sand. As a rule the vacuum varies between 3 and 10 in., and the vacuum air-pump and tables each require about 5 hp. to run. The pump drawing water from the receiver in which the vacuum is maintained requires about 3 hp., as does also that supplying the glands of the centrifugal pump which elevates the sand-solution pulp to the collecting vats. The last pump mentioned is the main source of power consumption and requires 40 hp. The plow is merely a thin steel sheet with a renewable wearing edge, and is capable of being raised and lowered so as to periodically remove the top compacted layer of the permanent bed. The maintenance on the slow moving tables (about one revolution in three minutes), is practically nil, though the usual wear on the centrifugal pump in handling even some sand takes place.

The recent remarkable development on the Rand of centrifugal pump elevation of pulp has greatly assisted in developing the method of solution-pulp transfer, and obviously the same plan could be adopted for transferring sand from the collectors to separately placed second treatment vats, but for new plants the superimposed vat system, when only shoveling down is needed, is still simpler and cheaper. The solution required for pumping the sand as pulp is about four or five by weight to one of sand; the ratio is kept as low as is compatible with the grade of the delivery launder or pipe. While collection is still proceeding, and before the vat is filled, the leaching off of solution from the vat is begun, and after the vat is filled as much more wash-solution is applied as there is time for before transfer, with the result that half to two-thirds of the

gold content of the sand is in the zinc boxes before transfer begins, and before treatment would commence at all under ordinary practice. Before delivering the sand-solution pulp to a collector the latter has three or four feet of precipitated sand solution pumped into it, the exact amount being regulated by that which is regularly withdrawn from the solution transfer circuit in the shape of solution leached from the collectors for precipitation; in this way an equilibrium of the stock of transfer solution is maintained, and at the same time its gold value is kept low, being usually under 0.2 dwt. per ton. It is found that the best work is done and driest sand obtained with the lowest vacuum; owing to the greater volume of air being drawn through with a more porous permanent bed; when the air has thus been renewed the moisture in the sand removed is about 13%, and this percentage slowly rises to say 19.5 immediately before the next renewal.

The slime overflowing the sand collector carries with it a small amount of fine sand, as is usual with a distributor, especially when the vat is nearly filled with sand. This sand may be intercepted on its way to the solution storage by means of one or more cone-classifiers, with the underflow gravity back to the sand-solution pump. As, however, the accumulated slime in the bottom of the solution-storage is periodically pumped to the slime-plant with solution, the fine sand may be removed at this stage by cones.

One somewhat unexpected result of the cone classification in the sand-filter installation is the appreciable increase in the slime-tonnage, which may be taken at about 40% of the weight of the ore in place of say 32% otherwise to be expected. This is mainly due to the separation as slime in the conical classifiers of 200-mesh sand.

The collecting vats employed to receive the almost slime-free sand-solution pulp may be of larger dimensions than usual, as settlement of slime in layers is not to be apprehended, and fewer larger units thus employed in place of more smaller ones. For the same reason the bulk of the lime used may be crushed with the ore in the battery, thus reducing the separate grinding of lime in a ball-mill or other machine to occasional periods when unusually acid ore is being delivered to the battery. Naturally the use of sand-filters greatly increases the capacity of existing plants whether of the superimposed or other type, by converting all the collectors into treatment-vats. The advantages which sand-filters present are considerable saving in capital expenditure both for sand-vats and belt or truck installation, slightly better extraction than the ordinary system, unless prolonged treatment is given, a saving with superimposed vats of belt or truck transfer cost, and more slime to be treated as such at, say, 6d. per ton less than sand in vats of slightly increased diameter. Evidence as to reliability in practice and low cost of operation has been given, and considerable extension of continuous sand collection both for new plant and for increasing the capacity of existing plants is now being designed or is actually in process of construction, so that within a year the present fifty odd thousand tons of sand handled monthly by this method on these fields is likely to be doubled or trebled.

ART OF PLACER PIPING.

Written for the MINING AND SCIENTIFIC PRESS
By DENNIS H. STOVALL.

Some superintendents and managers say that a good piper is half a placer mine. To the initiated this statement will not seem far-fetched. Without a good piper, or at least without a piper who knows a few of the main tricks of handling a giant, an otherwise payable mine will fail. The piper is the fellow who 'gets the stuff from the dirt', and it is 'the stuff' that counts. On the Pacific Coast, where gigantic hydraulic mines are common, 'piping' is an art. 'Pipers' are 'professional men', and proud they are of their 'profession', as they have a right to be, for piping is not picked up in a day. Like prospecting, engineering, and other phases and branches of the mining business, piping is an art that requires years to give perfection, or that degree of ability that men call perfection. Pipers demand and receive excellent wages, and there are few of them but earn every dollar that their pay-check represents.

To the expert placer-piper the roaring, singing monitor, that yields to the deflector's slightest touch, is, as it were, a living, breathing thing. A hydraulic giant is to him as a tamed lion to its master—obedient and powerful. None know better than he how best to swerve the big nozzle, to drive an avalanche of boulders down the gulch ahead of the giant's stream, scattering them like a handful of bullets shot from a catapult; or to bring that long, deep growl from the monster as it gnaws at the base of the towering red clay bank, till a great slab of a thousand tons topples and falls with a mighty crash from the mountain side. Clad from hat to boots in rubber and wool, the piper is at his post every day of the mining season, no matter how swiftly the wind may blow or how icily it may bite, or whether the rains pour, or the snows pile the diggings under a mantle of white—he is always there, directing the giant's powerful stream.

Other things being equal, the piper can remove the greatest amount of dirt in those diggings supplied with ample by-water, or 'by-wash', as he calls it. Without plenty of by-water to assist in driving the torn-down gravel to the sluices, the piper is greatly handicapped, for as much or more of his time must be used in 'driving' as in 'cutting', and all the time required for the former operation robs the bank of just that much time from the attention of the giant. Rather than operate a battery of three giants, it is best to operate only two, using the third for by-water, or to increase the supply of by-water already available, unless that supply be already amply sufficient.

It is not always the biggest or most powerful giants that remove the greatest amount of gravel within a given time. Too frequently the big giants must gnaw at the base of towering banks—banks so high that it is dangerous for the piper to approach closer than 300 or 400 feet—and thus the 'cutting power' of the stream is lost before the gravel is reached. The 'cutting power' is the main thing in the work of tearing down stubborn or cemented gravel. The 'cutting distance' of a stream varies, of

course, with the size and pressure, but most pipers estimate it within the range of the 'unbroken section'. If one will observe a hydraulic stream for a moment, it will be noticed that for a certain distance it is an unbroken shaft of white, the water being held to a direct course with scarce a curvature or downward drop. To strike the stream within this limit, is almost like striking a shaft of steel; to thrust the arm into it is to have the limb torn from its socket. Beyond this limit, however, the stream is broken, and has less cutting power. The piper attempts to keep his giant close enough to the bank to be within the cutting range of the giant's stream, moving the monitor as often as necessary.

The efficiency of the grizzly elevator in removing

A Piper at Work.

boulders from diggings which have not adequate dumping facilities, depends almost entirely upon the ability and adeptness of the piper. Even where grizzlies are not employed, the diggings are kept clean by the 'driving' of the piper. It is in these mines that a good piper is an absolute necessity; for otherwise the diggings would soon become hopelessly choked with debris. Where a grizzly is employed, the lead-race brings all of the gravel, by-water, dirt, and boulders from the diggings to the base of the elevator; the operation to this point is automatic, so to speak, but it is the duty of the piper to complete the performance. He dexterously separates the boulders from the finer stuff, and 'juggles' them up the incline, driving them like sheep up an inclined corral. Rocks, stumps, roots, and logs alike, find a common dumping-ground beyond the stacker. The

grizzlies, used by pipers in removing boulders and debris from flat diggings, are made from 10 to 15 ft. wide, and from 24 to 40 in length, with the sides boarded up to a height of 8 or 10 ft., and the whole setting at an angle of about 18 degrees. This raises the upper end from 25 to 30 ft. from the level of the bedrock, and gives ample dumping-ground for the season, the elevator being moved to another part of the diggings for the succeeding season. The floor of the grizzly is arranged with parallel steel crevices, like pole-riffles, running the long way of the elevator. While the boulders and coarse rock are being shoved up and over this by the water from the giant, the black-sand and the gold drop down into the crevices and slide back to the base of the grizzly and into the sluice.

MALM PROCESS IN COLORADO.

Written for the MINING AND SCIENTIFIC PRESS
By FORBES RICKARD.

The Chamber of Commerce of Georgetown, Colorado, has donated a mill-site to the Western Metals Co. The main retaining-walls are up, and the framing is about finished, for a mill-building of 50 tons capacity to demonstrate on a commercial scale a dry-chlorination process which has been perfected by John L. Malm, electro-chemist for that company. This plant follows years of patient experiment and research in developing this process and in working out improvements in its mechanical manipulation. In the last five years this is said to represent an expenditure of nearly a quarter of a million dollars and the scrapping of \$100,000 worth of machinery and apparatus. An experimental plant was first built in Corbin, Montana, in which the details of the process were worked out on tonnage basis, and in which many of the earlier difficulties of manipulation were overcome. The selection of this part of Colorado was presumably because the process aims primarily at the utilization of low-grade zinc sulphide ores, somewhat complex, with associated gold, silver, copper, and lead, of which there is an abundant supply in the district. Local conditions in respect to the making of a merchantable product are such that the intermediate process of concentration is indispensable under adverse conditions, in point of the saving effected, while for the smelter the precious metals are insufficient, with zinc, lead, and copper so proportioned in the ore as to fall under the minimum for which the smelter pays upon the existing schedule.

This process, in introducing an economical metallurgical practice where standard processes have stopped, has its field well defined. The Western Metals Co., of Denver, has purchased numerous patents growing out of the Swinburne and Ashcroft patents of 1897, which first gave prominence to a process which consisted, (1) in the conversion of the metal or metals in simple or complex sulphide ores into chlorides by the use of chlorine gas at a temperature of about 100°C.; (2) in the recovery of the metals by the substitution of one metal for another until zinc chloride alone remains in solution; and (3) in the electrolysis of the fused zinc chloride for the production of metallic zinc and the recovery of

chlorine. The chlorine gas is obtained through the electrolysis of common salt. As indicated in the foregoing paragraph the process is regenerative in respect to the chlorine, the loss in the entire cycle approximating 5 per cent.

According to Stuart Croasdale, who is consulting engineer for the Western Metals Co., this process has been in use in Europe for some time, both as an independent operation, and as a subsidiary to the soda industry for the utilization of chlorine. Mr. Croasdale has specialized in the volatilization of metals as chlorides, in collaboration with Edwin C. Pohle. In the mill practice of the Western Metals Co. the tube-mill temperature is kept below 100°C., but relatively higher temperatures are used in the Swinburne-Ashcroft and Bruner-Monde plants in England, which firms are manufacturing electrolytic zinc of a premium brand.

The several stages of this process as applied to the treatment of complex ores consist in, (1) crushing to 10 or 20 mesh; (2) tube-mill (porcelain-lined) grinding with partial chlorination; (3) tank agitation of pulp with water, steam, and chlorine gas, for complete chlorination. At this stage all metallic sulphides (iron, lead, copper, and zinc) are chloridized and sulphur is disassociated; (4) filter-press treatment to remove gangue and sulphur; (5) passing of the solution of metallic chlorides to granulated copper for gold and silver recovery; (6) passing of the solution of metallic chlorides to granulated zinc for lead recovery; (7) tank agitation with zinc oxide and chlorine gas to remove any iron and manganese present, which here becomes a by-product; (8) evaporation in vacuum-pans to dry and fuse the zinc chloride; (9) electrolysis of the fused zinc chloride for the recovery of the zinc.

In all this the substitution of one metal for another is based upon well known chemical reactions, while the granulated metals are produced from the general run of ore treated. It is calculated that theoretically one electrical horse-power, at 90% efficiency, deposits 19½ lb. of zinc in 24 hr., equivalent to 0.052 hp. per day for its production. In practice, in the Corbin plant, the actual recovery made was 14.2 to 14.4 lb. of zinc per horse-power day, or 0.07 actual horse-power per diem.

The cost of installation of the complete equipment is high as compared with other metallurgical plants, amounting to more than \$1000 for each ton of daily capacity. Thus, for the Georgetown plant of 50 tons nominal daily capacity the cost will be about \$70,000. In considering the subject of initial cost it may be taken into account that this process, in a continuous cycle of treatment, makes a bullion recovery of the metals in such a way as to supersede the several separate operations of concentration, smelting, and refining, with their attendant high costs of installation. In ores in which zinc predominates the lesser metals are figured to a zinc basis, and the cost is dependent upon that factor into the cost of the power at the point where the process is installed. Exhaustive tests have been made in determining the question of ore-supply available for the Georgetown plant. In these tests the treatment has been carried to bullion recovery, and percentage of recovery, figured on the

basis of bullion weighed out as against metal-contents determined by assay of the crude ore. Tests in the instance of the Griffith mine, representing an available ore supply of 60,000 tons, are said to have yielded a practical recovery of about 90%. The crude-ore assay, averaging several blocks sampled, gave:

| Metal. | Assay, oz. per ton. | Quotation, per oz. | Metal content. |
|--------------|------------------------|-----------------------|-------------------|
| Gold | 0.18 | @ \$20.00 | \$3.60 |
| Silver | 13.97 | @ 0.50 | 6.98 |
| | % | Per lb. | |
| Lead | 4.94 | @ 0.04 | 3.95 |
| Copper | 0.68 | @ 0.13 | 1.77 |
| Zinc | 9.00 | @ 0.05 | 9.00 |
| | | | \$25.30 |

Working out the marketability of this ore for purposes of comparison, this would, under the present smelter-schedule, require concentration to put it into a marketable product, and assuming a 25% loss in milling and a mining cost of \$3 per ton, it would leave a net profit of \$1.47 per ton. On the other hand, under contract with the Western Metals Co., the same ore, it is claimed, would admit of a return of \$6.85 per ton, which, less the assumed \$3 mining cost, leaves net \$3.85 per ton, after satisfying the charge imposed upon the ore by the owners of the process who buy the ore under special contract.

The Western Metals Co. proposes to put in mills under its ownership only, and not to make sale of the process under royalty arrangements. If not unduly delayed by the electric installation this company promises to have the Georgetown plant in commission this fall.

From the example just given it appears that with a recovery that exceeds 90% of the total metal content of the ore, the deviation of profit between producer and process-owner will be in favor of the latter. Whether such ore can be taken as representative of the general average of the Clear Creek district is questionable; a gross metal content of \$20 per ton would probably put the mark as high as could be reached in the average zinc-lead ores now available.

The Georgetown plant is destined to put to the proof a process which, while not altogether new in respect to the chemical principles used, is new in point of commercial development for a 50-ton unit, and its outcome will be watched with great interest.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

QUICKSILVER IN NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM C. DAVIS.

The Shoshone mercury deposit occurs in a highly silicious rhyolite as cinnabar, some calomel, and some meta-cinnabarite. This property is in Nye county, Nevada, about 50 miles south of Austin, Lander county, in the Shoshone mountains. This range is quite heavily wooded with nut pine and 'mahogany', and contains many little streams of water. There appear to be two veins, one with a northwest strike, the other northeast. Most of the development has been done on the northwest vein. It has been prospected on the surface by open-cuts

Shoshone Retort Furnaces.

at intervals for a distance of 600 ft., by 260 ft. of tunnels, and from the tunnel level by a winze and short cross-cuts. At present much of the ore is being taken from an open-cut, 35 ft. deep. The ore is sized on a fine grizzly and roughly hand-sorted. Ore thus sorted retorts about 6% merecury.

The reduction plant consists of an iron retort, of semi-circular section, built in series of threes, with one condensing box for each series. A retort is 8 ft. long by 24 in. wide, and holds four pans 18 by 20 in. A charge consists of 36 pans, each pan containing from 100 to 110 lb. of ore. Three charges per day are run. The retorts should be kept a cherry red heat. There is almost enough lime in the ore to make it self-fluxing, so that little trouble is experienced from the sulphur affecting the pans or retorts. Before each charge is drawn, the retort is blown with air, the free sulphur being thereby oxidized to SO₂. Some of the sulphur re-unites with the quicksilver forming a dark brown sulphide. Quicksilver has been found in two other places in the same vicinity, also in rhyolite, but, as yet, no development work has been done.

The size of the charge depends upon a combination of conditions largely determined by experience, by the size of the furnace, and by the relative amounts of the various ores to be smelted. These conditions here require on the charge 300 lb. of ore 'A'; 1200 lb. of ore 'B'; 500 lb. of ore 'C'; and 300 lb. of converter slag 'D'. The assays of these ores are given on the accompanying charge-sheet, which is a copy of the original at the smelter, with the ores represented by letter instead of by name. The pounds of the silica, iron, lime, sulphur, and copper contents of the ores are computed (generally by means of a slide-rule) and entered upon the charge-sheet. In choosing a slag to be made, it is not the practice at this plant to try to make an exact singulo-silicate ($2\text{RO} \cdot \text{SiO}_2$) or other exact class slag, but to make that slag which experience has demonstrated is best suited to local conditions. This experience-dictated slag, however, approaches a singulo-silicate, and if a new and untried one were presented for treatment calculation would be made for a singulo-silicate at the start. This matter of where to begin, what assumption to make in choosing a slag, is the crux of

be left, therefore, 15% for the matte, which amounts to 59 lb. In forming matte, Cu combines with one-quarter of its own weight to form Cu_2S .

$$\text{At. wt. Cu} = 63.6 \quad \text{Cu}_2 = 127.2$$

$$\text{At. wt. S} = 32.07 \quad 127.2 \div 32.07 = 4 \text{ (nearly).}$$

The amount of Cu in the charge has been calculated to be equal to $42 + 0.02x$. The amount of sulphur required by this amount of copper is therefore $\frac{42 + 0.02x}{4} = 10 + 0.005x$ (nearly), and the amount of sulphur left to combine with iron is $59 - (10 + 0.005x) = 49 - 0.005x$. In forming the matte the sulphur combines with 1.75 times its own weight of iron to form FeS.

At. wt. Fe = 55.9

$$\text{At. wt. S} = 32.07 \quad \frac{55.9}{32.07} = 1.75 \text{ (nearly).}$$

The amount of Fe required to satisfy $(49 - 0.005x)$ lb. of S $= (49 - 0.005x) \times 1.75 = 86 - 0.009x$. The total Fe in the charge, as per the calculation sheet, is 599 lb. from ores A, B, C, and D, plus 4% of the weight of the silicious ore $x = 599 + 0.04x$. Therefore the total Fe left to go into the slag will equal $(599 + 0.04x) - (86 - 0.009x) = 513 + 0.049x$.

[illegible]

the problem when beginning on an untried ore. Lang, in his 'Matte Smelting', considers the best slag to be generally a bisilicate of lime ($\text{CaO} \cdot \text{SiO}_2$) and a singulo-silicate of iron ($2\text{FeO} \cdot \text{SiO}_2$) in equal parts. The assumed slag in the present case is $44\text{SiO}_2 : 25\text{FeO} = \text{Fe } 19.5; \text{CaO } 0.23$. The problem is to determine the quantity of dry (silicious) ore containing high gold and silver content, and 2% copper, which can be put on the charge, and the amount of lime necessary to be added. The assays of these two materials are known, and are entered on the charge-sheet. Let the required amount of silicious ore be represented by x and the amount of lime by y . The total silica on the charge is that in ores, A, B, C, D, plus 69% of the weight of the silicious ore, x , plus 3% of the weight of the lime-rock, y ; 69 and 3 being respectively the silica content of the silicious ore and the limerock. Therefore the total SiO_2 on the charge is SiO_2 in pounds $= 765 + 0.69x + 0.03y$.

In like manner the total copper on the charge is the copper in the ores A, B, C, D, plus 2% of the weight of the silicious ore. Therefore, the total copper in the charge is Cu in pounds = $42 + 0.02x$.

As shown by the computed weights on the calculation-sheet there are 393 lb. of sulphur in the charge. It is assumed that 85% will be volatilized; there will

The total lime (CaO) in the charge, all of which goes into the slag, is 69 lb. from A, B, C, and D, plus 6% of the weight of the silicious ore x , plus 51% of the weight of the limerock y . This equals $69 + 0.06x + 0.51y$. Here now are three equations which give the pounds of silica and iron, and lime in the slag:

$$\text{SiO}_2 = 765 + 0.69x + 0.03y$$

$$\text{Fe} = 513 + 0.049x$$

$$\text{CaO} = 69 + 0.06x + 0.51y$$

In the chosen slag the ratio of the SiO_2 to Fe is

$$\frac{\text{SiO}_2}{\text{Fe}} = \frac{44}{19.5} \quad \text{Therefore} \quad \frac{44}{19.5} = \frac{765 + 0.69x + 0.03y}{513 + 0.049x} \quad \text{whence}$$

$$11.25x + 0.58y = 7700. \quad \dots \dots \dots (a)$$

In the chosen slag the ratio of SiO_2 to CaO is

$$\begin{array}{rcl} \text{SiO}_2 = & 44 & 765 + 0.69x + 0.03y \\ \text{CaO} = & 23 & 69 + 0.06x + 0.51y \end{array} \quad \text{Therefore} \quad \begin{array}{rcl} & 44 & \\ & 23 & \end{array} \quad \text{whence} \quad \begin{array}{rcl} 13.26x - 21.71y = & -14,570. & \end{array} \quad \text{(b)}$$

Solving equations a and b, $x = 629$ and $y = 1056$, the pounds of silicious ore and limerock respectively to be added to the charge. Entering these amounts on the charge-sheet, and calculating the respective quantities of SiO_2 , Fe, CaO, and Cu, there is found the total charge of 3985 lb., which will contain

| | Pounds. |
|------------------------|---------|
| SiO ₂ | 1231 |
| Fe | 624 |
| CaO | 646 |

| | |
|----------|-----|
| S | 393 |
| Cu | 55 |

The 55 lb. Cu on the charge will require $55 \div 4 = 14$ lb. S for the Cu_2S in the matte. The remaining sulphur, $59 - 14 = 45$ lb., will require $45 \times 1.75 = 79$ lb. Fe for the FeS of the matte. Therefore the matte will contain

| | |
|----------|---------|
| | Pounds. |
| Cu | 55 |
| S | 59 |
| Fe | 79 |

Assuming that these elements will comprise 95% of the matte, the other 5% being substances not considered, there results 203 lb. of matte, equivalent to a matte-fall of $\frac{203}{3985} = 5.1\%$. The resulting matte will assay $\frac{55}{203} = 27\%$ Cu. The slag will contain all the SiO_2 in the charge, 1231 lb.; all the CaO in the charge, 646 lb.; the Fe in the charge, 624 lb., taken up by the S in the matte = 545 lb., which is equivalent to 699 lb. FeO.

The slag is then composed of

| | |
|---------------------------|-----------|
| | Per cent. |
| 1231 lb. $\text{SiO}_2 =$ | 43.9 |
| 699 lb. FeO = | 24.9 |
| 646 lb. CaO = | 23.1 |

which is the slag intended to be produced.

For the sake of clearness this explanation has necessarily become long, but the method and its calculation is really not only short, but also most satisfactory. At the Garfield smelter the ore is dumped into bedding-bins and delivered to the furnaces, which are run by the appearance of the slag. The lime and coke in the charge are varied, or 'dope' charges are fed, according as the appearance of the slag, to the trained eye of the smelter man, seems to indicate. It is stated unofficially by an official that it has been two years since a charge was calculated here. The method used at that time is short and consists in assuming the charge, from past experience and the amounts which must be smelted, and calculating the resulting slag.

The accompanying charge-sheet shows the actual charge and the smelter's calculations. The charge consists of 2000 lb. of bed-ore, 2500 lb. of ore 'B', 500 lb. silicious ore, 500 lb. slag, and 500 lb. lime-rock. The amounts of silica, iron, lime, sulphur, and copper are calculated and carried out on the sheet. The volatilization of sulphur is assumed at 60%. There is then left for matte 167.4 lb. sulphur. Copper in the matte requires one-quarter of its weight in sulphur, or 62 lb. Thus $167.4 - 62 = 105.4$ lb. S is left to combine with the iron of the matte. Sulphur requires $1\frac{3}{4}$ or $\frac{7}{4}$ its weight of iron to form FeS. Therefore $105.4 \times \frac{7}{4} = 164.1$ lb. Fe required. This amount leaves 995 lb. to go into slag. Since Fe is $\frac{7}{9}$ of FeO, $995 \times \frac{9}{7} = 1278.9$ lb. of FeO in the slag.

The slag has now been determined. It contains

| | |
|----------------------|---------|
| | Pounds. |
| SiO_2 | 1786.0 |
| FeO | 1278.9 |
| CaO | 909.0 |

Assuming that these form 92% of the total slag, and that the other 8% is composed of Al_2O_3 , ZnO, etc., 4319 lb. of slag result; whence the above quantities give the following:

| | |
|----------------------|-----------|
| | Per cent. |
| SiO_2 | 41.1 |
| FeO | 29.6 |
| CaO | 21.0 |

The matte will contain

| | |
|----------|---------|
| | Pounds. |
| Cu | 248.0 |
| Fe | 164.1 |
| S | 167.4 |

Assuming that these constitute 95% of the total, there is a matte-fall of 610 lb., equal to 10%. The copper in the matte is 40.6 per cent.

THE KAPSAN MINES, KOREA.

*The ore is called 'whang chol', or 'yellow iron', the percentage of copper assaying over 20% in the first-class ore, and 5 or 6% in the second-class, an average of about 10%. The following is an assay by percentage of what is considered a common kind: Copper, 12.07; iron, 45.44; sulphur, 37.40; silica, 0.66. Lead, zinc, or other impurities are totally absent.

The Japanese authorities state that this mine was discovered over 1000 years ago by a Chinese who worked it without troubling himself to obtain a license from the Korean Government. Other authorities report the mine as having been first operated by the natives less than a century ago. The natives became acquainted with the richness of the deposit and took over the workings, continuing until 24 years ago when the ownership passed into the hands of the Imperial Treasury. The mine was worked by the latter for two years, during which it was in a very flourishing condition. Then again the mine became a private concern, the Imperial Treasury placing there, for the purpose of supervision and tax collection, a commissioner, who was conditionally an official contractor holding the post on paying the Imperial Treasury a certain annual sum as the revenue from the mine. In 1904 Americans were granted the right to operate at Kapsan, but this grant, as modified, was not confirmed by the Japanese protectorate until 1908. Heretofore the native Kapsan miners have solely resorted to manual labor, using a hammer called 'machi' and a drill called 'chung', until quite recently when they learned from foreigners the use of powder and dynamite. Before the Russo-Japanese war the greater part of the output was transported to Sin Chung, the port of Puk Chung, thence to be shipped to Wonsan seaport, where it was exported to Osaka by Japanese merchants. A portion went overland to Pyeng Yang or Puk Chon to be made the material for bronze casting.

Engineers who have examined the Djin Dong (Kapsan) mine are unanimous in stating that the ore possesses an average value of 10% in copper; that the mine, although only hitherto worked by crude methods, has yielded a substantial output for many years past, and that the indications point to the bringing into existence of a somewhat large and permanently profitable mining property, following preliminary development. The engineers agree that labor is cheap, efficient, and abundant, that plenty of timber is available for mining purposes and for fuel;

*Abstract from *Far Eastern Review*.

also that the existence of a sufficient supply of water for use in providing power is uncertain.

The present workings are situated about three-quarters of a mile from the eastern boundary of a limestone. On the top of the hill above the old workings there are small bands of shale embedded with the limestone. These dip about 30° to the southeast, which is more or less the general dip of the limestone in the neighborhood of the ore deposits, though it is so disturbed and has so many dips, from horizontal to vertical, that it would be difficult to give any figures as to the true average dip of the whole of the limestone. The Japanese government engineer states that the formation of this part of the country belongs to the Paleozoic, and mainly consists of alternate strata of limestone and marl in association with clay, slate, and sandstone. Those rocks have undergone the process of the contact metamorphism by the granite which outcrops at a point over three miles northeast of the mine, the limestone being crystallized and producing tremolite. Both the sandstone and the clay slate are also more or less metamorphosed. The strata have a strike from south to north, or from southwest to northeast, and lie in folds dipping west or east. Basalt covers the folds, or forms dikes running through them. The deposit is a formation made in connection with the ejection of the basalt, and consists of chalopyrite in association with pyrrhotite and arsenopyrite, containing no quartz. As a rule the boundaries of the veins are well defined, though some impregnation is traceable.

The ore is roasted, smelted direct, without the addition of any flux, in small clay furnaces and metallic copper is produced in two smeltings. Oxidized or especially rich ore is not roasted. The first ore mined was smelted direct, but when sulphides began to be worked difficulty was experienced until the present headman came from the Kang Kyei copper mine and taught the smelters to roast the ore. The ore is roasted in small circular stalls built of blocks of rock set in clay. These are 6 ft. in diameter and 4 ft. high. Roasting lasts from 16 to 20 days up to a month. Nine cents worth of firewood is used per stall to ignite the ore. Two samples of roasted ore were analyzed as follows:

| | No. 1, | No. 2, |
|------------------|--------|--------|
| | % | % |
| Sulphur | 11.00 | 14.32 |
| Iron oxide | 65.71 | 62.85 |
| Copper | 17.00 | 13.81 |

The roasted ore is smelted direct with the addition of some matte and slag from the second smelting. This first smelting takes 24 hours. Blast is provided by a large wooden bellows worked by a crew of six men. A matte is produced, which remains in the furnace, and a slag, which is run off and thrown away. The matte and slag had the following composition:

| MATTE. | No. 1, | No. 2, |
|---------------|--------|--------|
| | % | % |
| Sulphur | 15.70 | 17.40 |
| Iron | 22.30 | 23.60 |
| Copper | 27.82 | 32.28 |

The second smelting lasts 12 hours. The matte

produced in the first smelting, the roasted ore, and furnace scrapings from the final operations are melted to form (a) a slag which runs off and is thrown away, (b) a thick, clotted slag, which is scraped out and used again in the first smelting, (c) a cake of matte, which remains in the furnace, and (d) a circular slab of metallic copper, which is melted into a rectangular bar, and shipped.

| | SLAG. | |
|------------------------|--------|--------|
| | No. 1, | No. 2, |
| | % | % |
| Silica | 22.20 | 23.60 |
| Iron Oxide (FeO) | 54.66 | 52.77 |
| Lime | 2.40 | 1.30 |
| Copper | 2.45 | 2.30 |

The smelters have each his own smeltery, where they work a set of hearths, usually employing 6 blastmen, 1 bellows carpenter, and 1 assistant. In addition to board and lodging the carpenter gets 20c. per day, the assistant 17c., and the blastmen 13c., when they do a full day's work.

The process is similar to what is called in Japan the old-fashioned 'regular blast' process. The ores are first roasted in a circular cauldron resembling a stall. The roasted ores are then treated in a 'preliminary hearth', filled with charcoal, by a hand bellows. The mattes formed in this way are removed to a 'regular hearth', where they receive a finishing treatment, being fused with charcoal and firewood. The product of this treatment is the coarse copper. No other agents are used in the preliminary and regular hearths for the fusing, but, as is common in a process of this kind, the uneleaned slags formed in the regular hearth are again put into the preliminary hearth for further treatment.

As there are so many uncertainties, chiefly depending upon the scale of operations, the process of smelting employed, and what arrangements can be made for transport, and also what amount of stores have to be brought in, only rough approximations can be given at this stage. The mining will be cheap, and also ore transport, providing smelters are erected close to the mine. The estimated total cost of smelting is \$7.50 per ton. Transport to the coast can be arranged for at \$30 per ton, which includes both carrying copper to the coast and bringing back stores.

KINETIC THEORY OF SOLIDS.

In solids the effect of cohesive forces in the molecules is more apparent than in liquids. But since there is a transition from highly viscous liquids to plastic solids, and since many solids are known to vaporize without passing into the liquid state, and since solids may diffuse through solids, there must be a similar state of motion among the particles or molecules of a solid as in those of liquids. There is, however, much less kinetic energy in the molecules and molecular cohesion is more effective. When a solid is heated the kinetic energy of the molecules is increased, the effect of cohesive forces becomes less, the tendency of the molecules to separate from the solid increases. All solids possess a vapor tension, which at ordinary temperatures may be almost negligible, but at high temperatures become considerable, as in the case of platinum.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

English in Our Technical Journals.

The Editor:

Sir—The use of the English language, as displayed in some of the special articles in our technical journals causes one to wonder whether the writers of these articles are as careless with the subjects they treat as they are with the use of the language. One might think the large majority of the members of the engineering professions half educated. Surely a set of men cannot claim to be well fitted for any profession unless they are thoroughly prepared to express themselves. Refinement of language, besides giving tone to the results of experimental work, brings the thought out in a strong, logical manner. The objection that the technical schools cannot spend so much time on English composition might be well taken; but does this argument furnish a good excuse for the badly prepared technical man? There is certainly no excuse for any well educated American being unable to use his own language in such a manner that it expresses clearly all that he may wish to say.

The expression of thought in its logical sequence and relation is the purpose of language. Therefore, in the discussion of experimental data it is necessary that the thought be carried forward logically in order that the discussion itself shall not fail. It is not uncommon to see, in our technical papers, attempted compound sentences, in which the thought is completely lost in a jungle of semicolons, ands, commas, and parentheses. I have noted even the omission of the main verb. Is it possible that the writers of such badly composed sentences think clearly? There is another class of technical writers who seem to fear the compound sentence. In their work one may find a lot of short disjointed sentences which make the whole a failure, because there is no progression of thought. This is the main essential.

It seems to me that absolute clearness of expression is essential to the technical man. Every engineer, I am sure, will agree with me when I say that in any engineering work it is important that every detail be thoroughly and clearly understood. It has been well said: "every man can state clearly what he clearly understands." The reverse is perhaps also true. If an engineer fails to express himself clearly regarding the details of his professional work, how can his employer be sure that the engineer himself understands clearly what he is about to do?

The fact that the educational training of many untechnical men is beyond reproach, puts the technical writer in a delicate position in case any of his work is placed before such a man. If, in a report or professional article, the thought is confused and badly arranged, the well educated layman begins to lose faith in the writer. Such men in many instances furnish the capital for engineering ventures. It is

necessary, therefore, to have their absolute confidence if the ideas of the engineer are to be adopted.

I have known engineers to send material to the publisher without rewriting or revising it. Perhaps carelessness at the beginning accounts for the appearance in print of poorly written articles. It may be that many writers depend upon the publisher to make their work presentable. The publisher in all probability has troubles of his own and cannot assume a shifted responsibility. In any case the English of our professional men must be improved. The technical engineer has the responsibility of the advancement of civilization. His influence upon contemporary and future thought must be given consideration. Therefore, in order that the engineer's thinking may fulfil its purpose, his thoughts must be expressed with refinement and precision. There is also the esthetic side to the subject. The engineer deals only with the truth experimentally proved. All philosophy teaches that truth is beautiful. Ruskin believed that truth was beauty personified. Truth proved by experiment is the hand-maiden of modern philosophy. Why dress her in rags?

W. W. STRANGE.

Pony, Montana, September 15.

Metal Losses in Copper Slags.

The Editor:

Sir—The following communication to the secretary of the American Institute of Mining Engineers, brings up a subject on which great interest centres, and it may stimulate further discussion:

R. W. RAYMOND, Secretary American Institute of Mining Engineers.

In Lewis T. Wright's paper on 'Metal Losses in Copper-Slags', read at the New Haven meeting, he starts in by saying: "It is commonly believed by metallurgists that in copper smelting the copper in the slag, which is irreducible by continued smelting, is retained in the form of 'prills' of matte." On a recent visit to Greenwood, British Columbia, I was discussing with J. E. McAllister, general manager for the British Columbia Copper Co., and the former metallurgist for the Tennessee Copper Co., this very question, and he strongly held to the idea that the copper in slag was in two forms, namely, one portion contained in occluded matte, and the other as an oxide. He believed that this rule would apply also to the silver in the slag. From my experience I am strongly inclined to agree with Mr. McAllister; and it appears quite reasonable that in furnaces treating oxidized copper ores, and to a lesser degree in furnaces treating sulphide ores, there is always bound to be present a certain amount of copper oxide and silver oxide, which will behave like any base, and get into the slag as such. We all know that in Arizona, in the early days, when it was customary to produce black copper, because the ores were nearly all oxidized (or carbonates), and sulphur was scarce, the slags as a rule carried 2.5% copper and seldom less than 1.5%. The economic point was determined by the extra coke necessary to produce the reducing action. In connection with the extra saving in copper, Arthur L. Walker, now professor of metallurgy at Columbia University, and

formerly general manager for the Old Dominion Copper Mining Co. at Globe, told me that with coke at \$60 per ton it never paid him to make slags better than 2.5% copper.

In Tennessee, when treating well roasted and presumably well oxidized ore, we seldom, if ever, had our slags contain less than 0.5% copper, yet when treating this same ore pyritically, and producing the same grade of matte, the slag would not exceed 0.3% copper. The above instances are merely cited to show that the normal tendency of copper oxide is to act like iron oxide, lime, or any other base, and to go into the slag.

If we take Mr. Wright's first example and assume a 50% copper matte, corresponding with 0.3% copper slag, which, by the way, would be pretty low, we would have the following analysis of the matte and slag:

| | Matte. | Slag. |
|----------|------------|-----------|
| Cu | 50.000% | 0.300% |
| Ag | 31.400 oz. | 0.147 oz. |
| Au | 13.950 oz. | 0.026 oz. |

If we be permitted to assume that no gold is oxidized in the slag and that all there present is contained in the matte, we can assume the 0.026 oz. as a basis, and from it calculate the amount of silver and copper corresponding to the grade of the matte produced. I have given below, in the second column, the results of this calculation:

| | Total loss. | Matte loss. | Oxide loss. |
|----------|-------------|-------------|-------------|
| Cu | 0.300% | 0.093% | 0.207% |
| Ag | 0.147 oz. | 0.058 oz. | 0.089 oz. |
| Au | 0.026 oz. | 0.026 oz. | |

From the above it will be seen that of the total copper contained in the slag about one-third only is lost in the form of matte, and the other two-thirds is probably in the form of oxide. Nearly the same ratio exists for the silver; and we all know that silver is easily oxidized in a furnace with a hot-top, such as is usual in copper smelting, and, while no doubt part of it is volatilized, a portion of it is ready to go into the slag. While neither Mr. McAllister nor myself have any means of actually verifying the above theory, it appears to us the simplest and most obvious solution of the problem, and much more in keeping with the facts than that the metals themselves are dissolved in the reject material from the furnaces, which is a mixture of slag, with a small proportion of matte.

J. PARKE CHANNING.

New York, October 3.

Designing Mine Equipment.

The Editor:

Sir—Some months ago there appeared in the MINING AND SCIENTIFIC PRESS one or more letters on the subject of 'Designing Mine Equipment', a subject which should be of general interest. Max J. Welch, in your issue of June 12, asks the question, 'How can the chief engineer reduce the first cost', and answers it satisfactorily on the assumption that the chief engineer is intimately acquainted with the different types of machines and the special advantage of each. But the development of machines is so rapid that probably comparatively few men have

this expert knowledge. Reliable data are, furthermore, often difficult to obtain. The trouble is not, it seems to me, in designing a particular machine, that being the work of specialists, but in choosing from among the machines offered those which are best suited to the work, and which together will make a complete plant costing a minimum and giving the highest attainable result when in operation.

In Mexico there are many small mines capable of producing 20 to 50 tons per day where the design of a plant may make the difference between success, a partial success, or even failure. The difficulty is often more acute with the small mine than with the large one, because capacity may be of less importance than recovery, and as the ores are frequently of high grade an increase of even 1% in recovery bears a large proportion to costs. To give point to the discussion, I will assume a mine capable of producing 30 to 40 tons per day, the ore requiring fine grinding and cyanidation of the resulting slime, with or without previous concentration. The probabilities are that the mine will have a limited water or fuel supply, and the choice of power is of the first importance. It may be steam, producer-gas, or electricity if available. Since a producer-gas plant costs several times as much as a steam plant of the same capacity, how shall we determine which to use? If producer-gas is to be used, how shall we choose, from the plants offered, the one which, with our Mexican labor, will do its work day in and day out? For crushing, shall we use stamps or will a Chilean mill or other grinding machine give the larger profit? In a small plant might not a Chilean mill of large capacity be able to slime the ore in one operation and thus save the cost of a tube-mill or other re-grinder? If stamps are used, is there any advantage in the individual mortar? It is conceivable that in a large mill the care of the individual stamps might offset any advantages that they may have, but in a small mill there must be more workmen in proportion than in a large mill, and this disadvantage would disappear, giving the advantages, if any, a chance to show. For re-grinding, should we buy a long tube-mill of small diameter, a short tube-mill of large or small diameter, a conical tube-mill, or a grinding pan? For filtering the slime the choice is between the leaf filters, the continuous filters, and the pressure filters. A great deal has been published about the leaf filters and very little about the others. They are more recent, and may they not have advantages not possessed by the leaf filters, particularly in elimination of loss by osmosis?

Many more questions might be suggested, but these will illustrate the subject, and will, I hope, start a discussion resulting in some interesting and up-to-date data on the subject.

BYRON E. JANES.

Santiago Papasquiaro, Mexico, October 25.

Dolerite is an old term used, according to Pirsson, to designate the granular, igneous rocks, with predominant ferro-magnesian minerals, but in which it is not possible to tell positively just what ferro-magnesian mineral is present. This group therefore includes much that is commonly referred to as diabase.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Aerolites are meteorites of stony composition and are distinguished from siderites, the iron-bearing meteorites, by specific gravity as well as by composition.

Reasonable compensation for the daily services of a horse employed in a tunnel to draw cars or at a shaft in raising ore, and the like, may be treated as labor performed in assessment work.

Pitch-blende is likely to be confused by prospectors with several common minerals. Magnetite, sometimes so confused, may be distinguished by being attracted by a magnet. Hematite may be told from pitch-blende by its red streak. Obsidian or volcanic glass, most commonly mistaken for pitch-blende, differs from it in lower specific gravity, and in having a glassy lustre and light streak.

Felsite is a term used by Pirsson for quite dense rocks, light in color, and generally highly feldspathic in character, while basalt covers dense, dark-colored, igneous rocks, for the most part ferromagnesian in character. This usage gives both of these terms, felsite and basalt, a broader meaning than is customary. For example, dacites and most andesites fall under the head of felsite.

Fixation of atmospheric nitrogen may be accomplished by three groups of methods. First, direct formation of ammonia from its elements, both of which have to be isolated for the purpose. Second, the formation of metallic nitrides and cyanogen compounds, which are subsequently decomposed into ammonia compounds. And third, those methods which aim at the direct oxidation of atmospheric nitrogen to nitrites or nitrates.

Solution, especially in water, is a factor in effecting a change of speed in chemical action, usually promoting it greatly, but not always. The most pronounced action is effected through the ionization of one or both substances. Many substances are less active chemically when dissolved in water, as, for example, sugar. Moreover, most solvents, if they effect chemical change at all, retard it.

Sulphur in coal reduces its value, and such loss to the consumer is taken into account in corrections applied to purchase price by many large consumers, such as naval and other Government departments, municipalities, and the like. As an example, the Charles River Basin Commission of Massachusetts in its specifications to bidders demands a reduction of $\frac{1}{2}\%$ per ton for every one-hundredth of one per cent of sulphur in the coal in excess of one per cent.

Barium hydrate is used as a boiler compound. When bicarbonates are present, it precipitates calcium (or magnesium) carbonate and barium car-

bonate. If any alkaline earth sulphates are present, however, barium sulphate is formed and the bicarbonate decomposed by the hydrate liberated. It will be seen in this case that instead of remaining in solution, the reagent added is itself precipitated. It thus doubles the amount of suspended matter.

An ore-bin situated on a mining claim which has been open to location for several years becomes the property of one who makes a valid re-location of the claim. Improvements on ground open to location do not necessarily always belong to the locator. The placing of structures on such ground by mistake may give the builder an equity in them, and other circumstances may cause the courts to recognize the right of the original owners and allow of the removal of the structures.

Enantiotropism and monotropism are terms often used in discussing the change from one polymorphic crystal form of a substance to another. In some instances this change takes place with great slowness upon change of conditions; in other cases rapidly. In some, the transition may take place in either direction upon change of conditions; the process is then 'enantiotropic'. In other cases the transition is only possible in one direction, from a meta-stable to a stable condition. Such a process is 'monotropic'. Quartz and tridymite are enantiomorphic forms of silica, SiO_2 . A transition point between them occurs at about 800°C . Above this temperature tridymite is the stable form; below 800° quartz is stable.

'Lode' as used in the Acts of Congress has been held to be "applicable to any zone or belt of mineralized rock lying within boundaries clearly separating it from the neighboring rock. It includes * * * all deposits of mineral matter found through a mineralized zone or belt, coming from the same source, impressed with the same forms, and appearing to have been created by the same processes." It has also been defined to be a "body of mineral or mineral-bearing rock, within defined boundaries in the general mass of the mountain." The definition of a lode must always have special reference to the formation and peculiar characteristics of the particular district where the lode is found.

Annual labor, when performed on a mining claim by a lessee who holds an option to purchase from the owner, in order that it shall apply as annual labor on adjoining claims also owned by the lessor, but not under bond, must be sufficient in quantity, must actually benefit the adjoining claims, and facilitate the extraction of mineral therefrom. To remove all doubt as to the question of crediting such labor to the adjoining claims there should be an agreement between the lessor and lessee that the lessee shall perform such labor for the purpose mentioned, and this may be one of the considerations of the lease and bond. Where B and C own two claims and A has a half interest with B and C in a third contiguous claim, they may agree that all of the assessment work for the three claims may be performed on one of the claims.

Special Correspondence.

BRITISH COLUMBIA.

Boundary District.—B. C. Copper Co. — Rossland. — Nelson Shipments.—McGillivray Creek Coal.—Crows Nest Pass.

The ore shipments from the Boundary district for the week ending October 30, and for the year to that date were as follows:

| | Week, tons. | Year, tons. |
|------------------------|----------------|----------------|
| Granby mines | 25,332 | 827,382 |
| Snowshoe group | 5,050 | 122,004 |
| Mother Lode group..... | 11,572 | 242,764 |
| Oro Denoro group..... | 880 | 5,130 |

It will be noticed that the Snowshoe made a new record in last week's shipments, surpassing the former high-shipment mark for the week ending August 21 by over 620 tons. The Mother Lode gained about 200 tons over the high shipments of the previous week, while the Granby dropped a couple of thousand tons, owing to the breaking of the electric hoist at the Victoria shaft, and to the holiday for Thanksgiving day. The seven big furnaces at the Grand

British Columbia.

Forks smelter during the week treated 25,866 tons of Granby ore, breaking all former records.

The grading for the spur to the Phoenix Amalgamated group of the Consolidated company has now been finished, and the laying of steel will soon be under way. Shipments will be started to the Trail smelter as soon as this spur is in and things in running order. Work is to be started immediately on the extension of the Canadian Pacific railway from Phoenix to Wellington camp, where there is a heavy tonnage of ore awaiting shipment from the Jack Pot group, controlled by the B. C. Copper Co. This company is now about to make shipment of a 500-ton lot of Jack Pot ore as a test. This lot of ore will be teamed to the railway, and from there sent to the Greenwood smelter. In view of the increased tonnage now being received from its main mines, and of the future tonnage from the Jack Pot group, and the New Dominion mines at Phoenix, the B. C. Copper Co. is about to add increased smelting facilities to its Greenwood plant. It owns nearly 132,000 shares of stock in the New Dominion Copper Company.

The New Dominion Copper Co., through its Phoenix agent, John Seward, has paid up the old miners' wage-debt of the old Dominion Copper Co., amounting in all to about

\$20,000. Work is now under way tending toward an early resumption of mining operations. The Argo adit at Greenwood is now in over 200 ft., and penetrating a mineralized zone of good promise. It is planned to drive this adit 3000 ft. into the mountain, on which are several partly developed veins of gold-silver ore. The Hedley Mining Co. is going to add a steam plant to its water-power plant at Hedley, and with the hydro-steam power it will not be necessary to shut down when water is scarce, as in past years. The air-compressing plant will also be equipped for hydro-steam power. The Princeton Mining Co. will shortly make a series of test shipments to the Granby smelter, now that the Vancouver, Victoria & Eastern railway is completed to Princeton. The ore is low-grade and self-fluxing.

The ore shipments from the Rossland district for the week ending October 30 and for the year to that date were as follows:

| | Week, tons. | Year, tons. |
|--------------------------------|----------------|----------------|
| Centre Star group..... | 4,130 | 150,913 |
| Le Roi mine..... | 735 | 8,225 |
| Le Roi No. 2, Ltd..... | 420 | 25,062 |
| Le Roi No. 2, Ltd. (milled) .. | 225 | 12,795 |

It is gratifying to note that the Le Roi mine has again appeared on the shipping list, no ore having been sent from the mine since March 13 until the 21 carloads last week went to the Trail smelter. Shipments will not be up to the standard of the mine, nor steady for awhile, but will be sent to the smelter to avoid storage and to help pay the cost of development now going on in the lower levels of the property. Most of the ore shipped last week came from the lower levels of the mine where the gold predominates, and it is expected that the returns will be substantial. Part of the ore should assay from \$60 to \$70 per ton. With the advent of autumn the ambitions of the lessees have sunk somewhat, with the result that little or no work is going on at the smaller mines around the camp. At the Fife mines foundations and buildings are under way for the reception of the 100-hp. steam and air-compressing plant recently bought.

The ore shipped and milled in this district for the week ending October 30 and for the year to that date was as follows:

| | Week, tons. | Year, tons. |
|------------------------------|----------------|----------------|
| Blue Bell | 143 | 4,007 |
| Blue Bell (milled)..... | 900 | 42,368 |
| Cork | 21 | 448 |
| Emerald | 71 | 1,095 |
| Granite-Poorman (milled) ... | 250 | 10,168 |
| Kootenay Belle | 3 | 3 |
| Kootenay Belle (milled)..... | 70 | 2,873 |
| Nugget (milled) | 110 | 5,373 |
| Ottawa | 38 | 464 |

The Richmond-Eureka property of the Consolidated company shipped 150 tons of \$45 ore last week, after an absence from the list of shippers since July last. Rand Bros., of Vancouver, owners of the Dundee mine, Ymlr, are going to install a compressor and power-plant on that property and drive a long adit to tap the lead and upper workings at depth. A strike of free gold was made during the week on the Harold & Winne property, west of Erie. The Canadian Marble Works is now operating a force of 75 men and shipping 10 to 12 cars of first-class marble per week. A wagon-road will be built from Creston to Bayonne camp in the spring, when it is expected shipments of ore will be made from the Bayonne group, Montana, Summit

Bell, and Smuggler. On the Echo group of six claims in this district a small force is now at work. The ore assays as high as \$80 per ton. An up-to-date steel tippie is being built by the McGillivray Creek Coal Co., Carbondale. The company is shipping 150 tons per day, but is installing a plant to handle 6000 tons per day when the long entry is through. Substantial stone buildings are being erected by the company for machine shops and power plant. J. K. Cram, former engineer of the Centre Star group, Rossland, has resigned, and gone to Carbondale to take charge of the McGillivray company's property. L. A. Campbell, of Rossland, manager for the West Kootenay Power & Light Co., has been made a director of the company. It is expected the output of this company by the end of the year will be nearly 1000 tons per day. Approximately \$175,000 has already been expended on the property. The coal situation along the Crows Nest Pass is becoming better as the cold weather approaches. There is, however, a slight shortage of cars, which is somewhat of a drawback. The International Coal & Coke Co. is shipping 2500 tons per day.

TORONTO, CANADA.

New Goldfields. — Break in Stocks. — La Rose. — O'Brien Case. — Lands in Gillies Limit. — Government Peat Plant.

The Ontario Department of Mines is at present devoting considerable attention to the gold discoveries which have been reported from time to time in the region lying 40 to 50 miles south of the line of the Grand Trunk Pacific, and about 400 miles north of Toronto. The finds are in the neighborhood of the Temiskaming & Northern Ontario railway, which runs through this region in a northwesterly direction. For some time there has been a movement of prospectors from the northern towns and settlements, and many claims have been staked. Officials who have visited the field report that the discoveries are promising so far as the surface conditions are concerned, though the important question as to whether the gold continues in depth cannot now be decided. The principal staking is being done in the region around Porcupine lake in the townships of Tisdale and Whitney. Here the gold quartz is found in dikes, one of which has been traced for several hundred feet with a width of 60 ft. Free gold occurs in considerable quantities, and assays from sample crushings run as high as \$200 per ton. Other localities where gold-bearing quartz has been found are an area in Cody and Macklem townships bordering on Night Hawk lake, and another lying some 12 to 15 miles east of McDougall's falls on the T. & N. O. railway, embracing portions of the townships of Beaty, Munro, Hislop, and Guibord. Everything points to a big rush for this field followed by a boom in mining flotations early in the spring, but the prudent investor will remember Larder Lake and not put too much trust in reports of big strikes and sample assays.

Market conditions of late, even as regards issues of undoubted intrinsic value, have been anything but encouraging either to speculators or investors. The slump in Cobalt stocks has been almost continuous, the break in La Rose having apparently affected the entire list. The most unaccountable feature of the situation is that the operations of the market are not apparently affected by actual mining conditions. Big strikes and heavy ore shipments make no difference. During the two weeks ending October 23 while La Rose was steadily depressed the mine shipped a total of 447 tons of ore. The annual report of Mr. Watson, the general manager, shows a gross value of ore reserves on May 31 amounting to \$2,626,937, as against \$2,691,736 the year before, the slight decrease being due to the fall in the price of the metal. As Mr. Watson points out, much sinking and development remain to be done before the Lawson and other outside properties contribute materially to the total of ore production. The property is now under Canadian control, a majority of the new directorate being Montreal men. Coniagas has resumed the payment of dividends at the regular rate of 3% per quarter. The July dividend was passed, the money being needed to complete the concentrator. The shareholders of the Little Nipissing at a meeting held here on October 20 endorsed the recommendation of the directors

to increase the capital by \$500,000. Half the new shares will be offered to shareholders at 20c. per share. The Provincial mine, now operated by private owners, bids fair to make good. An orebody has been found at the 125-ft. level assaying about 1000 oz. per ton and diamond-drill tests have shown good results at 198 ft. At the Shamrock mine a rich vein 5 in. wide carrying native silver assaying 2000 oz. per ton was recently struck at the 200-ft. level, and shortly afterward another 4-in. vein was struck. One of the new veins on the Nipissing, No. 114, on being further uncovered widened to 6 in. carrying plenty of native silver. It will be reached underground by cross-cutting from vein No. 26 about 100 ft. distant and is expected to add largely to the output. The management of the Temiskaming has decided to sink from the 300 to the 400-ft. level. Good progress is being made with the installation of the new concentrator and only high-grade ore is being shipped. The shaft on the Waldman is down 85 ft., and the cutting of a station has been started at the 75-ft. level, where it is expected that a vein that dipped at a depth of 60 ft. in the shaft will be cut. Eight tons of ore have been sacked.

The peculiar ways of the Ontario Government in dealing with disputes between mine-owners are illustrated by the O'Brien mine case, which is recalled by the final payment made to the Alpha Mining Co. by the Government of \$100,000, the balance due of the amount of \$130,000 to be paid in settlement of its claim to the O'Brien property. The Alpha disputed the title of the O'Brien company, alleging a prior claim. The Government took the ground that if the O'Brien title was defective the lands should revert to the Crown, and induced the parties to accept a settlement, under which the O'Brien company was confirmed in its title, but subject to a royalty of 25%, and the Alpha company was to receive \$130,000 to be paid them out of the royalties collected. The last of this has just been paid over and the Government has in addition collected \$327,000 in royalties from the mine. The next sale of mining lands in the Gillies Limit will be subject to a new condition. Purchasers of the 1100 acres now offered must agree not to sell or dispose of their holdings to any corporation other than one chartered under the laws of Ontario, otherwise the patent is to be void. The reason is that previous purchasers have obtained Dominion charters giving them much wider powers than the Provincial Government is disposed to grant.

Eugene Haanel, of the Department of Mines, has installed the new government peat-briquetting plant at Alfred, Ontario. It was designed by A. Anrep, Sr., of Sweden, and erected under the superintendence of his son. It will be put in full operation next spring and will give employment to about 300 men.

Attention has recently been attracted again to the occurrence of tin ore near New Ross, Lunenburg county, Nova Scotia, and prospecting is now being carried on under the direction of Phil H. Moore. Tin was reported from that vicinity as early as 1868, and since 1906 considerable effort has been made to discover workable deposits. In 1907 the field was studied for the Canadian Geological Survey by E. R. Faribault, who reported that the Reeves tin deposit is a pegmatite segregation in the ordinary light gray granite of that region. Feldspar constitutes the greater part of the dike. Large quartz crystals, fluorite, tin ore, and other associated minerals occur in zones about the middle of the dike, in feldspar generally much decomposed. There is no well defined foot or hanging wall. The strike of the dike is N. 65° E. The dip is to the northwest and varies from 75 at the surface to 60° at the bottom of the pit. At the outcrop the dike was about 8 ft. in width and 12 ft. in length, but development shows that at one end at least it extends farther to the northeast under a cap of granite. The deposit is probably the result of deep solfataric action, and it should extend to a great depth. The results obtained so far should be considered satisfactory and they warrant much greater development.

The tin discovery has led to a good deal of prospecting in the vicinity of New Ross, with the result that several pegmatite, porphyry, aplite, and quartz dikes bearing economic minerals have been discovered.

KALGOORLIE, WESTERN AUSTRALIA.

Settlement of Labor and Water Prices.—Powder Wrappers.—Institute of Mine Surveyors.—Great Fingall.—Gas Engines. —August Output.

Two matters of much moment to the mines on the Golden Mile have been settled for another three years, namely, the wages agreement between the Chamber of Mines and the combined Labor Unions, and the price of water from the Government. Both agreements have been signed for three years. The wages remain as they were, which is satisfactory to all concerned. After a conference between the Mines' Water Trust and the Government, the latter has agreed to let the Trust mines have water at \$1.68 per 1000 gal. for ordinary uses, and 32c. per 1000 for sluicing away mill residue, the former price being in advance of 48c. per 1000. This will bring in about \$200,000 extra revenue annually for the scheme, but still there will be a large sum to be made up from the State's revenue for the sinking fund. Some few months ago at a meeting of the Chemical, Mining & Metallurgical Society of South Africa, it was suggested that the wrappers on explosives, as well as the explosives should be of some special color, so as to distinguish unexploded charges from the ore or rock. In Kalgoorlie it often happens that charges do not fully explode, and the powder goes to the mills with the ore. Now and again Griffin mills and other machinery have been damaged by the explosions. So far no accidents have occurred underground in handling rock mixed with explosives, but narrow escapes have been reported. The Chamber of Mines here has suggested to the manufacturers of explosives that they might wrap their products in some bright colored paper. They are now experimenting to find dyes that would be easily distinguishable from the ore, and yet have no effect on the explosive.

The Kalgoorlie branch of the Australasian Institute of Mining Engineers meets once a month now, and some interesting papers are discussed. The best known surveyors in this State have formed an Institute of Mine Surveyors, the idea being to get Government certificates for the members so as to give them legal status as qualified mine surveyors, to secure uniformity of practice among mine surveyors, to advise on the training of surveyors, and to discuss professional questions. This is certainly a move in the right direction, especially where so many are following this profession. In the Chamber of Mines Monthly Journal is an interesting article by the manager of the Great Fingall mine, on stopping the flow of water from a bore-hole and surrounding country by pumping in first sawdust and then cement, the result being that the entire flow ceased. This system of stopping leaks by pumping in cement has been very successful in America, according to all accounts.

Good results are reported from development in the Great Boulder, Ivanhoe, and Golden Link at 2500, 2120, and 500-ft. levels respectively. The Great Fingall is not so good again in the winze below level 14.

The use of gas engines in Western Australian fields is steadily increasing, although at present there are only a few hundred horse-power in use. Wood for steaming purposes is getting scarcer and dearer. Good charcoal can be made out of the local wood, and suction-gas plants are working here costing about 1.5c. per horse-power. This is cheap work; and so far the engines have given little trouble.

The August gold output from the State was valued at \$2,540,000. The principal mines produced as follows:

| Name. | Tonnage. | Value. | Profit. | Dividend. |
|--------------------------|----------|-----------|----------|-----------|
| Associated | 11,645 | \$105,000 | \$30,000 | |

NEW YORK.

Copper Shares and the Copper Combine. — La Rose.—Ely Stocks.—
Union Copper —Guanajuato Consolidated.

The copper situation has developed into one of extraordinary interest. Some heavy sales of copper have been made by the United Metals Selling Co.; sales of sufficient magnitude to affect the present surplus to a marked extent, and while the aggregate amount is not definitely known, it is anticipated that the forthcoming statement of the Copper Producers' Association will be the best the Association has been able to make this year. There has been a marked advance in Amalgamated, Butte Coalition, Greene-Cananea shares, and the prevailing tone is altogether hopeful and anticipatory of better conditions. The 'copper combine' has been the subject of almost endless discussion, and it is evident that matters are taking form as rapidly as possible. The announcement just made that two Phelps-Dodge directors are to go on the Greene-Cananea board, is evidence of the closer relations existing between the Cole-Ryan and Phelps-Dodge interests. It is pretty well understood that the belligerent attitude of the Guggenheims has been overcome, and that in this one of the chief obstacles to harmonious working out of the situation has been removed. There are many explanations, theories, and denials from all quarters. In the general comment the gravity of the undertaking is hardly appreciated. Any adequate organization to protect the market for the metal or to control a major part of the production of the country must be unusually powerful. Nearly every important financial interest of the country should be directly or indirectly represented in any such combination and the magnitude of the undertaking can only be realized by those familiar with the situation. So large and important an undertaking must move slowly, but apparently progress is being made.

The annual report of the Nevada Con. for the year ending September 30 has just been made public. It shows a production for the year of 34,527,823 lb. of copper and a net profit for the year's operations of \$1,646,062. The average assay of the ore treated was 2.34% copper while the average extraction was 70.73%. Copper costs were 7.14c. per lb. or loading copper costs with all possible charges including an item for rental of the Steptoe plant 7.47c. per lb. During the last quarter of the fiscal year production was 14,265,788 lb., and the report predicts that during the coming year production will be 6,000,000 lb. of blister copper monthly. At the annual meeting of the company held at Portland, Maine, on November 2, the old board of directors was re-elected and the proposed increase of capital stock was approved; the increase being the 400,000 shares which is to be exchanged for Cumberland-Ely. The Goldfield Consolidated report mailed to stockholders with checks for the fifth quarterly dividend, while showing that the company was earning a fair margin above its dividend requirements, was not favorably received and the stock declined somewhat in the market. The shares of the La Rose Consolidated have been for some weeks the centre of attacks by traders, whose movements have somewhat mystified both stockholders and the general public. There has been selling in volume and under strong pressure, culminating in a drive this week which carried the stock from \$6 to \$4½. On Thursday the announcement was made that the board of directors after a trip of inspection and a thorough examination of the properties had issued a statement that the dividend would be cut from 16 to 8%. It is quite evident that there was some inside selling before the announcement was made public. Had it not been for some investment buying by the outside public the market demoralization would have been much greater. The directors

explain that it is their intention to build up a cash reserve with which to more broadly develop the property. It is also reported from inside sources that the Lawson 'silver sidewalk' fails to hold grade at the 100-ft. level. Market-wise, the Ely (Nevada) stocks continue to hold the attention of the traders. There has just been a setback in the market campaign in Ely Central, which is built upon spectacular advertising. The stock sold last week as high as \$4, which, on the company's \$16,000,000 capital, is on a basis of \$6,400,000 for the property. Taking into consideration the fact that all that Ely Central will have to spend upon development is the proceeds of a bond issue of \$600,000, said to be already underwritten below par, recently provided for by an increase in capital stock from \$12,000,000 to \$16,000,000, the bonds to be convertible into stock at \$1.50, it would appear to say the least, that the recent market price was quite unwarranted by any conservative analysis of the situation. Union Copper Mines, of malodorous memory, is evidently preparing to repeat, if possible, its performance of some years ago, when a scandalous manipulation of the stock culminated in the bursting of the bubble after the shares had been forced upward from \$1 to \$42 per share. Some reports made ten years ago are being revamped and the names of eminent engineers are being mentioned in connection with present

Guanajuato, Mexico.

efforts to bring the shares into public favor. Quotations are ranging around \$4 per share and active trading is maintained to entrap the gullible market followers who are more interested in quotations than in mine valuations. Recent results in the Guanajuato Consolidated mill are said to have a tendency to show that close concentration as practised there will almost justify letting the tailing run into the river instead of maintaining and operating the company's large cyanide plant. Parish MacDonald is said to have remarked the other day that if it came to the question of equipment of a similar property it is doubtful whether a large cyanide plant would be advisable. A small re-grinding and cyanide plant, it is said, might be profitable for treatment of the slime. The Guanajuato Consolidated is reported to be putting in Diester concentrators. These are said to be making a good saving and to reduce the silica by 2% over previous standards.

MEXICO.

Oil War.—Taviche Shipments.—Zinc Ores and Smelting.

The oil war between the two great rival oil powers in Mexico, the Waters Pierce and the S. S. Pearson interests, has been going on for a long time, and has reached the amusing stage of almost daily bulletins in the press, where each company candidly states that it is selling below cost, with the hope of eventually driving the other competitor out of the field, and freely advises the general public to buy all the oil that it can while prices are low. In some advertisements the public is advised to buy from the rival, it being pointed out that the more the rival sells the sooner will it have to go out of business. It is the generally accepted opinion that the Waters Pierce, the Standard Oil, and the Harriman interests in Mexico are all closely allied,

and that the S. S. Pearson interests control the greatest extent of the Mexican oil-fields. There is a tariff against the importation of crude oil if it is to be refined and sold in the country, but oil can be imported free of duty and refined in bond, provided it is exported again within a year. There are frequent rumors that the oil-fields of Mexico are not as good producers as reported, and that a great deal of salt water is pumped up with the oil, and that there are indications that they will not be able to meet the demands. It is well known that refineries owning extensive oil-fields in Mexico have been forced to import large quantities of crude oil for lack of supplies of proper quality and in sufficient quantity from their own wells. During the drilling of a deep well for the Harriman interests a 2½-in. drill-stem was twisted off, when the well had reached a depth of 3800 ft. As soon as the broken piece can be removed, drilling will be continued until the well reaches 4000. No oil has been struck since the first slight flow of several months ago. When finished this will be the deepest hole in Mexico. Oil-well drilling has been making good progress close to the mouth of the Topola river, 30 miles from Tampico, under the control of the Mexican Fuel Co. Charles Nelson is in charge of operations. He is considered one of the most experienced drillers in the country. Oil was found at 2450 ft. and 6 ft. of oil-bearing sandstone was drilled through and cased off; the oil was of 17° gravity. Following this an 8-in. stratum of hard-pan was drilled through, and a second bed of oil-bearing sandstone was cut, which yielded high-grade oil. As a result of the indications so far found it is thought that this well will prove one of the best producers of Mexico. The Mexican Fuel Oil Co. is drilling on land near the Tamesi river. Well No. 2, which was recently brought in, has a depth of 1150 ft., and the oil is of about the same quality as that from the Ebano fields, with a specific gravity of about 11° Beaumé, and a flash point of 198°F. As considerable pressure has developed, the well has been closed with a valve. The product has been contracted for by the Waters Pierce Oil Co., which will build a pipe-line 2500 ft. from the storage-tanks to the Tamesi river, from which point it will be conveyed by barges to the company's refinery at Tampico. The Mexican Fuel Oil Co. owns about 13,000 acres in the district.

The Pearson interests have struck good oil at the Camp Tumbadero fields near Tuxpám. The well was drilled through the asphalt belt; this was cased off, and then came over 1000 ft. of shale, and under the shale petroleum, with a paraffine base, was encountered. It is of a good quality and of yellowish brown color. There is not sufficient pressure to cause a flow, and so the well has been capped and another will be drilled in the immediate vicinity.

It is reported that over 1,000,000 acres of oil-bearing lands in the State of Tamaulipas have been bought by California capitalists. The tract is known as the Rancho Limón, the purchase price is said to be \$2,500,000 United States currency. Part of the Tampico division of the National Railroad runs through the property, and the railroad stations of Las Palomas, Rodriguez, Cocos, and Auza, are all within the territory. Added to this the Panuco river is within reach, and is navigable for light-draught boats at all seasons. There will be no lack of shipping facilities for the products, and Tampico and the Gulf ports can easily be reached. It is stated that a large number of oil seepages are known to exist on the property and that drilling operations will be started at once.

Owing largely to the cessation of the rains, but also to the improved grade and quantity of ore taken out of the San Juan mine, there has been a considerable increase in the total amount of ore shipped from Taviche during October. It is also reported that ore will soon be shipped from The Ocotes mine of the Teziutlán Copper Mining & Smelting Co. which is situated at Ejutla. This mine is the second largest in the State and has not been shipping ore for nearly two years.

The smelters are being affected by the curtailment of the amount of ore shipped. This is due largely to the increased milling facilities, and to the success obtained in treating the low-grade ores by concentration and cyanide. The decrease in the shipment of dry silver ores is also due to the

low price of silver. It, therefore, looks as though the smelters will have to re-adjust their charges, and silica will no longer submit to be penalized as it will be needed for flux. Parral, which was the largest producer of silicious ores in the north of Mexico, is now treating nearly two-thirds of its output in mills, and as soon as the Palmilla mill is erected, very little silicious ore will be shipped from that camp. This mill will have a capacity of about 1000 tons per day. It also looks as though the smelters may engage in a rate war, as the Velardeña concern has offered a flat rate for freight and treatment-charges on all ores shipped from Guanacevi, which will in part meet the demand made by mining men for concessions by the smelters in regard to silica-charges, which now amount to 20 centavos for each 1% of silica. This sometimes works out as high as \$8 to \$12 per ton, which is an absolute bar to the development of low-grade properties.

The American Zinc Extraction Co., operating mines on the Cerro de la Cruz, at Parral, is now sinking a new 3-compartment shaft. The mouth of the shaft is at a slightly higher elevation than either the main railroad track, or the mill, and is distant about 150 ft. from the former and 600 from the latter. Three new Huntington mills have been already erected and a complete new plant of the Elmore flotation process is being added to the concentration plant. It is stated that this is the first installation of the Elmore process made in Mexico. The Parral Consolidated Mines Co., operating in the same district, has nearly completed its new concentrator, which was delayed by having a carload of machinery lost in transit. José Maria Botello, who owns the Apodequeña mine, in the same locality, has started to open the property again after it has been closed for several years. Two shafts are being sunk, one of which is in shipping ore. In a former letter reference was made regarding a prospective zinc smelter to be erected at Sabinas, but the promoters of the enterprise do not seem to have been able to finance the deal. There is a new project on foot, backed by Alfred E. Rodriguez, vice-president and general manager of the Cigarrera mine in Chihuahua. Rodriguez is a representative in Congress from that State, and has the support of the Federal Government and the backing of a number of influential bankers. It, therefore, seems highly probable that he will succeed in floating the enterprise. Data have been collected, and careful estimates made, regarding the possible output of zinc mines in Mexico, and it has been decided that a smelter with an immediate capacity of 600 tons per day and an ultimate capacity of 1000, would pay well. This appears to be estimating up to the limit of possibilities. As far as is generally known the Mexican output has not exceeded 60,000 tons per annum. It is not quite plain what could be done with all the spelter that would result. It seems hardly likely that smelting could be done here so cheaply that it would pay to export the spelter to the United States or Germany. If the problem of electric smelting of zinc ores had been satisfactorily solved then there would be a real field in Mexico in view of cheap power from the hydro-electric plants. It is stated that Torreon has been selected as most suitable for the erection of the proposed Rodriguez zinc smelter, as being near the zinc mines. This raises the question whether it is cheaper to place the smelter near the coal mines, and haul the ore to the coal, or the reverse. This, like many other smelting problems in Mexico, depends not only on the relative bulk, and tonnage to be hauled, but on the direction of grade on the railroad lines and on freight rates. The coal could all be handled in bulk in large shipments and might be subject to special rates; but ore, especially high-grade ore and concentrate, comes in small lots from a number of different points, and though in the aggregate it might amount to a large tonnage, it would, according to National Railroad line charges, be subject to maximum rates. This brings up the whole question of railroad rates in Mexico, and the national policy in this regard. It is thought by some mining men that as the railroad rates, the tonnage hauled, and the income from the railroads directly affects national income, it might be worth while for the government to consider the advisability of making special low rates on certain ores.

SALT LAKE, UTAH.

Boston Con. Plans.—U. S. Smelting, Nevada.—Zinc at Good Springs.

Frank A. Schirmer, director and treasurer, and Hugh Jennings, director and consulting engineer of the Boston Con., have been inspecting the property at Bingham and the mill at Garfield. The object of the trip at this time is to learn the conditions of the mines as the year draws to a close, and make some recommendations to the directors with regard to development and improvements for the ensuing year. One of the first considerations will be the enlargement of the capacity of the mill, in order that the output may be increased. It was the original intention to erect a reduction plant with a 6000-ton capacity, but opposition was made to the adoption of the plan of A. J. Bettles to introduce stamps, instead of Chilean mills. A number of the large shareholders in the East took the position that the Utah Copper must have adopted the best method, as D. C. Jackling had conducted a series of experiments at the Coperton plant before he finally decided upon the Chilean crushers. Mr. Bettles was allowed to construct an experimental plant near the mine with five stamps. The Eastern directors sent a number of experts to inspect the workings, and it developed that for some reason a very low extraction was being obtained. At first engineers insisted that it was the fault of the mill, and it was only after repeated tests of the tailing that they were convinced that the porphyry near the surface was very low in grade. These reports caused the directorate to allow Mr. Bettles to put up the present Garfield mill, but the company decided that it should be of less capacity than originally planned. This precaution was taken as it was argued that possibly a higher-grade ore might not be found in large deposits, or that the fault might yet be found to be with the process of reduction. A change was made in the operations at the mine, and the steam-shovel work was stopped. Tunnels were run to reach the ores at greater depth, and the tally-sheets in a short time showed a higher grade of ore. The concentrate began to give a higher return from the first units of the new mill and orders were given to get the mill in position to handle an increased tonnage as fast as the ore could be blocked out. The only delay at the mill has been occasioned by failure to deliver the tonnage required from the mine. The underground workings have been extended and the consulting engineer now advises the company that the mine is in position to double its output. The recovery in the mill has satisfied all interests that one of the best processes has been adopted, and the recommendation to the directors to double its present capacity of 3000 tons is sure to carry.

Conditions at Contact, Nevada, are encouraging. During the summer, the United States Smelting Co. took a bond and option on a group of copper claims and has been developing the ground on a large scale. A few days ago a fine body of copper was uncovered, and arrangements are now being made to increase active operations. The camp is situated in Elko county, near the boundary line of Idaho, and while the extent of the copper deposits has not been determined, it is high grade, and can be shipped some distance. The railroad is within 30 miles of the camp, and will be completed during the winter months. With the assurance of a considerable tonnage of this ore, it is said that the company has decided to complete its copper furnace in Utah and ship the ore to this point. Operations in the zinc properties at Good Springs, Nevada, have been greatly stimulated as a result of the high market price for this metal. Samuel Newhouse and associates, of Salt Lake City, are heavily interested in the district, and some high-grade deposits of zinc and lead have been developed. In one property a 50% zinc and 50% lead ore is being blocked. Some of the zinc buyers have visited the district and are prepared to make a good price for the ore, but some heavier equipment will have to be installed before regular shipments can be contracted.

Copper output from the mines of Utah for October approximates 10,500,000 lb. This will be increased during November as the Ohio Copper mill will be started.

General Mining News.

ALASKA.

(Special Correspondence).—The Vermont Marble Co. has purchased the marble properties at Takeen, Marble island. George C. Robinson is in charge of the development work.—Development of the Red Wing Copper mine in the Ketchikan district is now going on under the management of C. T. Moore.—At the Moonshine Chomley, Ltd., William Rea, the foreman, reports having struck an 8-ft. vein of rich galena ore at a depth of 140 ft. Some of the samples assay as high as 1500 oz. silver per ton.—A force of men is renewing operations on the Cuprite property, west coast, Prince of Wales island. J. T. Jones is manager.—The proposed 2000-ft. adit at Seal bay is now in 900 ft. Several veins containing a good percentage of chalcopryite ore have been cut.—An ore barge sprang a leak while loading at Mount Andrew, and had to be run aground. The ore amounting to about 3200 tons will probably be recovered.—This season has not been favorable for the prospectors on account of the excessive rainfall.

Ketchikan, November 1.

The Alaska Northern Railway Co. is to operate trains as far north as the rails are laid this winter to carry supplies toward the new camp of Iditarod, as there has been a large influx of prospectors and the provisions of the camp are limited. The route from Valdez is 1200 miles while from the end of the railway it is 400 miles through a country that supplies can be hauled on sleds.

ARIZONA.

COCHISE COUNTY.

The No. 8 cross-cut on the 500-ft. level of the Shattuck-Arizona mine in the Bisbee district, opened a body of copper oxide, samples from which assayed 15% copper. A. B. W. Hodges, the recently appointed general manager, is to visit the property shortly, and it is understood that the company will again consider plans for a reduction plant.—The California & Paradise Mining Co., which recently took over the Leadville claims in the Paradise district, is to install pumping machinery at the property and unwater the inclined shaft. The company is building a surface plant and shipping in supplies. W. V. Richards is superintendent.—The Consolidated Mines Co., at Tombstone, is installing two Prescott pumps on the 800-ft. level, the combined capacity being 10,000,000 gal. per day. An accident last summer to the pumps on the 1000-ft. level allowed the water to rise to the 800, and with the former equipment it was impossible to drain the mine. W. F. Staunton is superintendent.—The October output of the Copper Queen smelter was 9,400,000 lb. of copper, and that of the Calumet & Arizona plant 4,500,000 pounds.

GILA COUNTY.

The Scorpion shaft of the Inspiration Copper Co. has cut through the carbonate zone and is now in a chalcocite ore that assays between 2.25 and 2.50% copper. It is the intention of the company to sink to the 300 or 400-ft. level before cross-cutting. A new Fairbanks-Morse pump has been installed on the 400-ft. level of the Joe Bush shaft.—The Warrior Development Co. is shipping 75 tons of 10% copper ore per day from its property in the Miami district to the El Paso smelter. The drifts on the 250 and 300-ft. levels and the raise from the 300 are all in ore of the same grade.—The Arizona Commercial Copper Co. is shipping 20 tons of matte per day to the Old Dominion plant. The county surveyor is making a preliminary survey of a wagon-road from Globe to Copper Hill, and the spur of the Gila Valley railroad to the latter place will be completed by the end of the year.—The winze on the fifth level of the Gibson Copper mine, at Gibson, opened a 6-in. vein of high-grade ore.—The Tonto River Mining Co. has resumed work at its property 70 miles north of Globe and is shipping in supplies from that point.

MOHAVE COUNTY.

In the monthly bulletin issued by the management of the Golconda zinc mine, the production for October is given as

800 tons of ore, estimated at \$18,000, shipped to the smelter, and about 1000 tons of milling ore placed on the dumps. The expenses, including all costs of development, amounted to approximately \$10,000, leaving a net profit of about \$8000.—At the Expansion mine, in the Union Pass district, six miles from Goldroad, foundations for the three 40-ton cyanide tanks are nearly completed, and three of the six stamps for the new mill are in place. The air-compressors are being moved and will be housed with the mill. At the Tragedy group, adjoining, the adit is in 260 ft., and has cut several stringers of quartz.—The shaft at the Gold Bug mine, in the Weaver district, is down 500 ft. A station will be cut at that level, and a drift run to the ore-shoot.—A. L. White, D. S. Richards, and Walter Fellows, have secured a bond on the Midnight property near Chloride, and will commence development at once. Mr. Fellows will be in charge of the work.

PINAL COUNTY.

The drift in the Argosy workings of the Vekol mine, at Vekol, opened a shoot of rich ore estimated to contain approximately \$50,000.—The shoot on the 300-ft. level of the Copper Creek mine, 14 miles east of Mammoth, was intersected by the cross-cut on that level. On the 200 it was

Power Plant, Copper Queen Mine.

50 ft. wide all being a good grade of ore from which several shipments were made. A shipment from the 300 will be made shortly to test the commercial value of the ore.—The Development Company of America has purchased the property of the Saddle Mountain Mining Co., and a large interest in the London-Arizona company at Saddle Mountain, and will commence work on the properties at once. The company will try to have the properties in such a condition that shipping can be started to the smelter at Sasco as soon as the Phoenix & Eastern railroad is completed. The deal includes over \$1,500,000 worth of property upon which a large amount of development has been done. W. J. Martin will manage the affairs of the company at Saddle Mountain and Charles E. Finney at the London-Arizona.—Development will be started on the London Mountain group shortly. There are 53 claims in the group which is controlled by E. B. O'Neill.

YAVAPAI COUNTY.

M. J. Nolan, administrator of the Farley and guardian of the Kay estate, granted an option on the Farley and Kay claims in the Columbia district to Harry G. Brown, W. D. Achauer, and Charles K. Mellon, for two years. There are nine claims in the group upon which a stamp-mill has been erected. This will be put in good condition and the ore crushed to ascertain the most advantageous method of treatment. The property has a good record in the past, while the ore crushed was taken from the oxidized zone.

CALIFORNIA.**AMADOR COUNTY.**

The management of the Rhetta mine, near Plymouth, shipped 280 lb. of high-grade ore to the '49 Rush, at Stockton, for the mineral exhibition and two tons to the Selby smelter.

INYO COUNTY.

(Special Correspondence).—The attachment for \$7832 against the mines and smelter of the Four Metals Co., at Keeler, has been released by order of the court, the company having given bonds to cover the amount. It is currently reported that the Four Metals Co. has effected a consolidation with the Western Ore Purchasing Co. Steady shipments of bullion are being maintained. In the Cerro Gordo mine high-grade ore has been opened from the 600 to the 1000-ft. level.—The Gray Butte company is opening a 6-ft. body of milling ore. George E. Austin is superintendent.—The Skidoo management reports the improvement of the main vein with depth. The mill is running steadily.—At the Keane Wonder the copper content in the ore continues to increase with depth. This property is the largest producer in the county, keeping the 20-stamp mill steadily in operation.—At the Bishop Creek several bodies of milling ore are reported in the shaft. Assays are reported to run from \$10 to \$250 per ton.—It is announced that the Virginia & Truckee railway will be extended through the mineral districts of Inyo and Mono counties. This will enable a large number of low-grade properties to operate.—The Tecopa company is shipping steadily to Utah smelters. Developments in the Gunsight and Noonday mines continue satisfactory. There is apparently no ground for the continued report that this company is about to acquire the Needles smelter, as the management is understood to be considering the erection of a reduction plant near the mines.

Bishop, November 5.

LOS ANGELES COUNTY.

The Los Angeles Chamber of Mines has received notification from a number of the railroads that the Pacific Freight Tariff Bureau has been instructed to include in the next tariff a provision granting a free rate on all ore and oil specimens consigned to the Chamber from points on their lines, and intended for exhibition purposes. This free rate is now effective on some of the lines and will become effective on the others within a short time. The following railroad companies have granted the concession mentioned: Southern Pacific company, and all connections, including the Southern Pacific lines of Mexico; the Santa Fe and connections, including the Tonopah & Tidewater and the Bullfrog-Goldfield; the Tonopah & Goldfield; El Paso & Southwestern, and the National Railways of Mexico; also the Salt Lake route.

NEVADA COUNTY.

At the Giant King mine, near Washington, the lower adit is expected to cut the vein in a short time. This will give the company 900 ft. of backs on a vein that is 100 ft. wide in places. The mill is running steadily and the capacity of the compressor plant is to be doubled in a short time.—A new road is being graded from the Emigrant Gap highway to the Yellow Metal mine at Bowman's dam, to bring in the supplies for the new mill under construction at the property.—The large station pump at the 1250-ft. level of the Prescott Hill mine, near Grass Valley, has been moved to the 1750 and drifts started on the vein. This will open a large amount of unprospected ground and give the company a chance to increase its tonnage.—A new pump has been ordered for the Kenosha mine and the shaft will be sunk below the 600-ft. level before any cross-cutting is started.

PLACER COUNTY.

W. P. Hammon has purchased the Fairview quartz claim, Crater Hill Extension, and Young Crater Hill claims in the Ophir district from Louis Kittler and E. C. Turner, and it is understood that a 10-stamp mill will be erected on the property.

SHASTA COUNTY.

The bag house of the Mammoth Copper Co. is to be com-

pleted about April 1 next year, is the statement of Fredrick Lyon to the committee from the Shasta County Farmers' Protective Association. A. S. Haskell has resigned as superintendent of the Mammoth smelter at Kennett and has been succeeded by G. W. Metcalf. Mr. Metcalf has been in the employ of the United States Smelting, Refining & Mining Co., at its Salt Lake plant, for several years.—The American mine, in French Gulch, was sold at auction to Edward Sweeney and A. J. Treat for \$20,869, that being the amount of the operating company's indebtedness.—The copper ore recently cut at the Spread Eagle group, operated by the Onn Copper Mining Co., above Copley, proved to be on top of the main orebody and an adit has been started 65 ft. further down the hill.

SIERRA COUNTY.

The vein at the Rainbow Extension property, in which a rich shoot was opened recently, has widened from 18 in. to 3 ft., all being a good grade of milling ore.—The assay office at the Rainbow mine, at Alleghany, was broken open and \$5000 worth of bullion from the last clean-up taken.—C. C. Crary and J. C. Spencer have purchased the Yellow Jacket mine, at Alleghany. Mr. Crary will be in charge of operations at the property.

TUOLUMNE COUNTY.

The management of the Manganate mine, near Jamestown, is to install power-drills at the property.—At the Republican mine the water has been lowered below the 300-ft. level and the drifts are being re-timbered and put in shape for active mining.—The power company has strung its wires to the Draper mine, at Soulsbyville, and a complete electric-power plant has been installed at the property.—Work has been temporarily suspended in the adit at the Last Chance property. This is now in 500 ft. and will require some 300 additional feet of driving to bring it under the ore found in the upper levels.—The water in the lower levels of the App mine resulting from a flow of water from the 1000-ft. level of the Dutch mine has been removed and operations resumed on the 1300-ft. level.—The shaft at the Black Oak property is being put in good condition and work will be resumed in the mine as soon as there is enough water in the ditch to develop power.

COLORADO.**LAKE COUNTY.**

The shaft at the Little Vinnie mine, near Leadville, has been re-timbered to the 430-ft. level and will be sunk to the 700-ft. level. A new compressor has been installed and surface buildings erected.—John Cortillini and associates leasing the Grand Prize property on Breece hill, have resumed work in the upper levels of the mine.—A new pumping plant has been installed at the Progressive shaft on Fryer hill.—A new plant is being installed at the Adelaide shaft. S. P. Fenton is in charge of the work.

OURAY COUNTY.

The Thistledown Mining Co. has commenced work on a dam and ditch to develop electric power for the new mill for which the company has just broken ground. The plant will generate 250 hp.—Contractors have commenced work on a new adit at the Frank Hough mine that will be 2500 ft. long when completed, and will allow the shipping of ore all winter.—The Revenue power plant No. 3 has been started and the force at the mine increased. The mine is in good condition and the production will be somewhat over 100 tons per day.

SAN JUAN COUNTY.

At the Gold Prince mine, at Animas Forks, the 40-stamp mill is running steadily and sending a high-grade concentrate to the Durango smelter.—A large body of high-grade ore has been opened at the Columbus mine, operated by W. M. Johnstone, and shipments will be sent out as long as the weather permits.—The Little Dora mill, which was shut down for a short time on account of the blockade, has resumed operations and will be turning out concentrate rapidly from now on.—The main working adit at the property of the Peerless San Juan company cut a body of rich ore several hundred feet below the old workings.—The ore-shoot which was opened on the fourth

level of the Silver Ledge mine, had been found on the third and the management plans to sink and cross-cut for the ore on the fifth level. J. B. Ross is operating the property under lease.

SAN MIGUEL COUNTY.

The Favorite Mining Co. has been incorporated to develop a group of claims in the Ophir district. The company has secured the Suffolk mill and will equip it with new machinery. A large amount of supplies has been taken to the mines for the winter and a contract let to build a 4000-ft. tram to the mill.

SUMMIT COUNTY.

The adit of the King Solomon company, at Frisco, is now in over 3500 ft., and has cut 10 veins. On No. 4 west, a drift has been run with good results, and on No. 4 east, a raise is being driven in ore.—At the Arctic mine on the Blue river, a new 10-stamp mill is nearly completed and will be in operation some time this month. There is a hydro-electric plant at the mine and the company is breaking the ground with electric drills.

TELLER COUNTY.

The progress for the month of October in the Roosevelt tunnel was 380 ft., making a total of 11,400 ft. The heading is now in the Pike's Peak granite on Beacon hill.—The production for the past month of the Trilby mines was 750 tons, approximating \$15,000 in value. The mill is now running and the output has been increased to 70 tons per day.—October proved a banner month for the Cresson Consolidated Mining & Milling Co., the output being 3500 tons. A cross-cut is being driven south on the 1000-ft. level toward the properties of the United Gold Mines Co., on Battle mountain, upon which the Cresson company holds a lease.—The 40 sets of lessees in the El Paso Consolidated company's ground shipped 2000 tons of ore in October, the average value of which was \$25 per ton.—From the main shaft of the Mary McKinney property, on Battle mountain, the Western Investment Co. shipped 809 tons of ore in the month, assaying between \$25 and \$30 per ton.—Two thousand tons were shipped in October by about 35 sets of lessees from the holdings of the Granite Gold Mining Co., the gross value of which amounted to \$56,000.—The Vindicator Consolidated Gold Mining Co. mined a total of 2800 tons which approximated \$30 per ton. Of this 1500 tons came from the 1300 and 1400-ft. levels of the main Vindicator workings, 800 tons from the Hull City shaft, and 500 from the Vindicator No. 2 under lease to Whitney & McMullen.—There are 40 sets of lessees working in the Stratton Estate properties and the combined output for the month amounted to 2000 tons of \$25 ore.—The Colorado & Pike's Peak Consolidated Mining Co. is to resume operations at its property north of Cripple Creek and may build an experimental mill to test the value of the ores.—The Pride of Cripple Creek Leasing Co., operating the Pride of Cripple Creek mine on Ironclad hill, have installed a new hoist and are constructing a new head-frame and ore-bins.—The Western Investment Co., of Victor, has secured a two years' lease on the Empire State mine on a graded royalty basis, the leasing company paying from 15 to 45% of the value of all ores marketed.—The group on Galena hill, owned by the Homestake Gold Mining & Milling Co. is to be opened to lessees.

IDAHO.

BONNER COUNTY.

The bankruptcy proceedings against the Idaho Smelting & Refining Co. have been dismissed and operations will be resumed on the construction work of the company's smelter at Ponderay. J. Herbert Anderson is president of the company.

CUSTER COUNTY.

It is reported that a stamp-mill will be erected at the Sunbeam mine at Sunbeam in the spring. Werner Ziegler is in charge of the property.

IDAHO COUNTY.

The adit at the Golden Crown mine cut a 6-ft. vein of good milling ore. John Massam is in charge of the work.—Both dredges in the Elk City district are running and will continue until compelled to close down on account of

cold weather. The machines are working on the bedrock and good clean-ups are expected.—Operations are to be resumed at the American Eagle mine on Seigel creek.

OWYHEE COUNTY.

As a result of the investigations of the engineer that examined the property of the Silver City Mining & Milling Co. for English capitalists, J. F. Cook, the manager for the company, will make a trip to London to confer with the directors of the syndicate that wish to acquire the property.—At the Banner mine, near Silver City, the company is building snow sheds from the mine to the mill to prevent any shortage of ore during the winter months.—At the Big Sugar Loaf the lower adit has cut a 4-ft. vein at a depth of 1100 ft.—Arrangements have been made to adjust the affairs of the Potosi company and work will be resumed at the property at an early date.

SHOSHONE COUNTY.

The Hercules Mining Co. has secured power from the Washington Power Co., and will operate the old Tiger mill recently leased by the Hercules management until a new mill can be built at the mine to take the place of the one recently destroyed by fire.—Work has been resumed at the face of the drift on the Mark Cooney group, near Burke. The vein was opened by a 700-ft. adit and a 100-ft. drift when operations were suspended. There is 2½ ft. of galena ore in the face and it is understood that arrangements are being made for a sale.

NEVADA.

ESMERALDA COUNTY.

An injunction was granted by Judge Farrington in the Federal District Court on November 6, restraining 35 assayers at Goldfield from buying concentrate or high-grade ore without giving notice of such purchase to the officials of the Goldfield Consolidated, Combination Fraction, and Florence companies. The statement was made by the complaining companies that over \$1,000,000 had been stolen in the past two years through the sale of concentrate and high-grade to the assay offices.

HUMBOLDT COUNTY.

Lessees operating the Mazuma Hills property in the Seven Troughs district received \$6000 from a shipment of 80 tons of ore crushed at the Mazuma mill. A pump has been installed and the mine will be opened below the water level.—At the Buckhorn mine the lessees have opened a good grade of milling ore at a number of places and are considering the joint erection of a mill to treat the ore as the haul to custom mill at Mazuma cuts too deeply into the profit.—At the Dayton lease the cross-cut has opened several feet of milling ore.

NYE COUNTY.

(Special Correspondence).—The Pioneer lease has resumed underground work and is shipping three carloads of ore, which was stored in the bins.—The Mayflower is driving from the 400-ft. level to cut a shoot of ore which was recently opened between the third and fourth levels, assaying \$50 to \$75 per ton. The shaft is being sunk from the 500-ft. point. The main object is to secure a larger flow of water for the mill.—A 2-ft. vein said to assay \$175 per ton has been cut on the 400-ft. level of the Rattlesnake property of the Bonnie Clare company. Ten additional stamps and a branch line from the Nevada-California power system have been contracted for, the entire plant of 20 stamps to be in operation by the first of the year.—An 8-ft. body of milling ore has been opened in the Signal Peak.—The shaft at the Johnnie is down 700 ft. with several veins of milling ore intersected. A 10-ft. Chilean mill has been added to the plant, which contains 16 Nissen stamps. This increases the capacity to 120 tons per day.—The Nevada-Johnnie company is sinking from the 60 to the 100-ft. levels, and will cross-cut from this point.—The Belmont mill, at Millers, has been closed several days while an ore-washer was being installed at the mine. Officials state that recent developments in the lower levels have been most satisfactory. On the 1100-ft. level the showing is exceptionally good. It is possible that the plant will be moved from Millers to Tonopah after the shaft has passed the 1500-ft.

level.—The two raises from the 300-ft. level of MacNamara are in ore and that from No. 5 stope has cut the orebody opened by the west drift.—It is reported that E. G. Wheeler and associates, of Philadelphia, are considering the erection of a large custom mill at Tonopah. It is planned to install a plant to treat the low-grade ores of the district.—A 10-stamp mill is being installed at the Tonopah Liberty and a cyanide plant will be later erected. Thomas S. Carrahan is superintendent.

Rhyolite, November 6.

STOREY COUNTY.

During the last week in October 442 cars were hoisted at the Ophir mine assaying \$42 per ton. This was taken from six different portions of the mine, 26 cars of high-grade coming from the south drift on the 2000-ft. level which accounts for the high average.—At the Mexican mine 60 cars were hoisted from the 2300-ft. level that assayed \$38 per ton, and work has been resumed on the 2100 and 2200-ft. levels.—In the Sutro tunnel repair work has been advanced rapidly, about 700 ft. of pipe having been set in the ditch.

WHITE PINE COUNTY.

The controlling interest of the Carbonate Ely Copper Co., operating in Sawmill canyon, 35 miles south of Ely, has been purchased by Jesse Knight from Charles A. Walker and Gilbert F. Boreman. There are 15 claims in the group upon which a good showing of copper with some silver and gold has been made.—The Eureka Fraction shaft, at the Ely Central, is down 200 ft., and a No. 7 Cameron pump installed. The company shipped 40 tons of ore from the Clipper claim to the Garfield smelter.—The stockholders of the Nevada Consolidated company voted for the consolidation with Cumberland-Ely, exchanging one share of the Consolidated stock for three and one-quarter Cumberland-Ely. The October production of the Nevada Consolidated amounted to 208,000 tons, all of which was handled by the Steptoe Valley plant. It is probable that the fifth unit will be added at the smelter and the total production of the consolidated properties brought up to 10,000 tons per day.

UTAH.

SUMMIT COUNTY.

At the Scott Hill property, in the Park City district, the company has started an adit 200 ft. below the level of the winze sunk on the contact some time ago. Some excellent ore was found in the winze and the management expects to open a commercial body with the adit.—Drifts have been driven 300 ft. in each direction on the vein at the 1700-ft. level of the Daly-West property, the entire distance being in good ore. It is understood that the mill will be run on three shifts in the near future, increasing the output to 600 tons per day.—At a meeting of the stockholders of the American Flag mine, at Park City, it was decided to increase the capital stock of the company and to either drain the lower levels of the mine by a connection with the Ontario tunnel or to install heavy electric pumps.—The Western Monitor company has completed a surface plant and living quarters for the men at its property in the Uintah district, and is planning the erection of a complete electric plant at the mine with a generating station in White Pine canyon.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—An aerial tramway, of the Northwest Iron Works make, has been installed at the Gold Eagle mine at Blewett, and hydraulic equipment has been put in for the G. H. Snowdon mine at the same place. These installations were made under the direction of George W. Otterson, of Seattle. A small mill is operating on ore from these properties. Half the gold in the ore is saved on amalgamating plates, the other half in concentrate that assays \$45 per ton. R. G. Sargent is superintendent of both properties.—The Cascade Consolidated Mining & Smelting Co. is opening a group of mineral claims that surround Doubtful lake, near the summit of the Cascades, in which they find a good grade of ore carrying gold, silver, and lead. The lake named, forms the headwater of Stehekin river,

that flows into Lake Chelan. Udo Hesse is consulting engineer and W. A. C. Rowse, of Seattle, manager.

Blewett, November 6.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Placer Gold Mines Co., controlled by Seattle and Boston men, for which T. M. Daulton, of Seattle, is manager, operated one giant six weeks this season on Ruby creek, 17 miles from Atlin, after having finished the 4000 ft. of ditch, flume, and pipe-line, which gives 337-ft. head of water. The company's placer holdings extend from the mouth of Ruby creek up stream about 3000 yd. During the past season much of the ground was thoroughly prospected to bedrock, by sinking shafts and running drifts, showing an average pay-gravel 35 ft. deep. It is stated that portions of the ground yields \$5.75 per cu. yd. Most of this is gravel, which readily disintegrates when the stream of water at high-pressure is brought to play against it. Mr. Daulton states that he will put in a full season's work next year with two No. 6 giants, and he anticipates handling 200,000 yd. during the season. The other companies which are hydraulic mining in this

Map of Washington.

district are the North Columbia Gold Mining Co., J. M. Ruffner, manager, operating 12 giants; Pittsburg & British Hydraulic Mining Co.; Spruce Creek Hydraulic Co., William Hall, manager, operating three giants; Henri Maluen Syndicate, two giants on Otter creek; Boulder Creek Hydraulic Co., one giant, T. O'Balski, manager; Birch Creek Hydraulic Co., two giants on Birch creek, and the Guggenheim properties on Pine creek.

Atlin, November 4.

(Special Correspondence).—The Canadian-American Exploration Co., made up of Cleveland and Toronto capitalists, is developing a group of claims on Valdez island, and another on Las Queti island. The first has a contact vein between limestone and diorite, the ore being chalcopryrite, accompanied by some tellurium, assaying 4% copper and \$4.60 per ton gold. The vein is about 8 ft. wide. The second group contains a fissure vein of chalcopryrite and gold ore. The work is being done under the direction of Percy Williams, of Vancouver.

Vancouver, November 6.

ONTARIO.

The extension of vein 114 at the Nipissing property has been stripped for 250 ft. Of this, 50 ft. was high-grade ore 3 in. wide. During the winter a cross-cut will be driven to the vein from the 85-ft. level of No. 26 shaft.—The cross-cut from the 200-ft. level of the Shamrock property opened a vein of calcite with 4 in. of silver.—The Union Pacific Cobalt Mining Co. has purchased the Michigan mine which adjoins the Farah and Silver Leaf for \$240,000. Of this, \$140,000 was cash, the balance to be paid in five years. Some excellent prospects have been uncovered on the surface of the property and a shaft sunk 120 ft.—The Crown Reserve management has opened a vein of rich silver ore on the Silver Leaf ground in a cross-cut from the 100-ft. level of the Silver Leaf shaft.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. C. MENDENHALL has gone to Seattle.
 EDWARD LAUBE is at Lucky Boy, Nevada.
 M. K. RODGERS, of Seattle, has gone to New York.
 P. C. STOESS, of Seattle, was in California last week.
 H. F. A. RIEBLING, of Denver, is in southwestern Utah.
 A. E. DRUCKER has gone to London from South Africa.
 EARL R. PEMBROKE has returned to Salt Lake from Montana.
 JOSÉ MONTERO, of Guadalajara, was in San Francisco this week.
 ERLE V. DAVALER is with the Utah Copper Co. at Garfield, Utah.
 G. S. EVANS, of Silver City, New Mexico, has gone to London.
 J. M. CLEMENTS has returned to New York from the Southwest.
 J. P. KEANE, of Wallace, Idaho, recently visited Portland and Seattle.
 EMERSON GEE has returned to Los Angeles from Indianapolis, Indiana.
 G. A. SINGER, of the Gold Dredge Mining Co., has returned from Nome to Seattle.
 R. W. SHOEMAKER, recently with the Federal Lead Co. in Missouri, is in Arizona examining mines.
 V. V. CLARK, manager of the Bunker Hill mine at Reiter, Washington, has returned from California.
 ARTHUR K. ADAMS has gone to Phoenix, Arizona, as mineral inspector for the General Land Office.
 G. P. JONES is now general superintendent of the Nickel Plate mine and mill, Hedley, British Columbia.
 L. W. BARNETT, of London, who has been at the Tomboy mine, Smuggler, Colorado, has gone to Mexico City.
 ARTHUR E. HEPBURN, mining engineer, has opened an office in the Winch building, Vancouver, British Columbia.
 E. NELSON FELL and W. PELLEW-HARVEY have dissolved partnership. The name of the new firm will be Pellew-Harvey & Company.
 A. W. TUCKER resigned from the Seaboard Copper Co., in the Virgilina district, to become general manager for the Union Copper Mines Company.
 F. F. SHARPLESS has returned to New York from Colorado, where he examined the Alice mine for the Consolidated Mines Selection Co., of London.
 ROBERT LINTON, of Atwater, Linton & Atwater, has been appointed general superintendent for the Sierra Mining Co., with headquarters at Ocampo, Chihuahua.
 W. H. WEED and FRANK H. PROBERT have recommended to the Proprietary Mines Company of America the purchase of the Tajo de Dolores mine at Guanajuato, Mexico, control of which is under option to the Proprietary Mines company, at about \$1,000,000.

Obituary.

CHARLES S. NICOL died at his home at Mill Valley, California, on October 29, at the age of 79 years. He was one of the early pioneers on the west coast, going to Vancouver, British Columbia, in 1859, and was for nine years general manager of the Vancouver coal mines. He was afterward general manager of copper mines in Spain, and subsequently for the Smelting Company of Mexico, at Chihuahua. He was the first magistrate appointed in British Columbia.

Dividends.

On Thursday, November 4, the BUNKER HILL & SULLIVAN M. & C. Co. paid dividend No. 146 of \$45,000. This makes the amount of dividends paid since January 1, 1909, \$570,000, and the total to date \$11,241,000.

COMPANY REPORTS.

BROKEN HILL PROPRIETARY.

During the half year ending May 3, 1909, the work at the mine in the Barrier Ranges silver field, and at Port Pirie, South Australia, was suspended owing to labor troubles five months out of six, so that costs were completely disorganized. Only the smelting, refining, and zinc concentrating plants ran steadily, these at reduced cost. In the report of the company there is none the less much of interest. In the European conferences of lead producers the Broken Hill Proprietary Co., Ltd., was represented by the chairman of the London board. The statement that the agreement effected specifically states that its object is "the regularization of lead prices, but not to create an artificial level," is to be noted. It is stated that the object is only "to obtain such control of the disposition of lead in such markets and ways as will maintain a regular range of prices to such extent as the law of supply and demand may allow."

CONSOLIDATED M. & S. CO. OF CANADA, LIMITED.

This company owns an important group of mines in British Columbia, including the Centre Star and War Eagle, St. Eugene, Richmond-Eureka, Phoenix, and Snowshoe (leased), together with the Trail smelter. A statement of production from these mines was published last week. In the report for the year ending June 30, now available, additional details are given. Since the company commenced operations \$1,309,731 has been expended on capital account. Shares to the value of \$656,400 have also been issued to acquire new properties, leaving \$144,800 unissued. It has therefore been decided to increase the authorized capital from \$5,500,000 to \$7,500,000. The operations for the year show a net profit of \$329,004, after writing off \$153,218 for depreciation of plant, \$16,650 sundry items, including bad debts, \$24,444 on account of cost of placing Richmond-Eureka upon a producing basis, \$563,413 charged to profit and loss on account of development, and \$56,000 to absorb loss in metal quotations. The net credit, including \$32,061 carried over from last year, stands at \$361,066. During the year additions to plant to the amount of \$164,957 have been made, land costing \$22,070 bought, and \$55,766 paid for new properties and for development, all out of operating profits. The smelter is now treating the output of the Canadian Metal Co. regularly. The gross value of the metals produced during the year was \$5,505,526, making a grand total to date of \$36,700,000.

LA ROSE CONSOLIDATED MINES COMPANY.

The production from this property for the fiscal year ending May 31 last shows a production of 6173 tons. The reported ore reserves developed are 4583. In addition are 5747 tons of rock, other than vein material, containing silver to the extent of nearly 80 oz. per ton. Thus a total of 10,330 is reached, having an estimated gross value of \$2,520,142, on which a profit is anticipated amounting to \$1,729,038. The costs are figured on the same basis as for the previous year, namely, 30.69% of the gross value. The low-grade ore is to be concentrated under contract with the Northern Customs Concentrators, Ltd. This local concern will treat the ore now on the dumps as well as the silicious ore extracted in the regular course of mining. During the year 3269 ft. of driving was done in the La Rose mine, 410 of raising, 125 of shaft sinking, and 1684 of cross-cutting. The most important development on the other mines of the group consisted of shaft sinking, 72 ft. on the Princess, 91 on the University, and 34 on the Violet.

The output for the year was 6173 tons of ore, containing 3,005,363 oz. silver, yielding a net value of \$1,363,039. The operating expense was \$259,089, or \$42.73 per ton, equal to 8.89c. per ounce of silver recovered. Total cost of production was \$475,562, or \$78.43 per ton of ore, working out at 16.31c. per ounce of silver. The marketing expense consisted of smelter deduction on silver \$87,396, treatment

charges \$47,359, transportation \$61,525, analysis, smelter representatives, and insurance on ore \$9,977, making a total of \$206,258, or 13.60% of the gross value of the ore. The following table gives the tonnage of various sorts of ore produced and their corresponding silver contents:

| | tons. | Silver, oz. |
|-------------------------------|----------|----------------|
| Silver-cobalt-nickel ore..... | 1,671.82 | 2,264,896 |
| Low-grade silicious | 4,318.52 | 604,646 |
| Low-grade cobalt | 39.84 | 1,288 |
| Concentrate | 31.62 | 18,528 |
| Nuggets | 1.86 | 26,347 |

The company estimates its properties to represent an asset of \$7,463,595. Other assets bring up the total to \$7,995,487. Capital stock outstanding, at par value, equals \$7,535,644. There is on hand a surplus and undivided profit of \$421,481.

BUNKER HILL & SULLIVAN.

The report of the Bunker Hill & Sullivan Mining & Concentrating Co., just issued, shows a total income for the year ending May 31 last of \$3,453,691. Disbursements were: freight and treatment on ore, \$1,333,660; operating expenses, \$761,374; other expenditures, \$428,807; dividends, \$825,000. A balance remained in the hands of the treasurer of \$99,337. Ore reserves blocked out amount to 3,071,682 tons. During the year 344,470 tons were treated, but the new plant just completed will admit of local treatment of 40,000 tons per month, so that, including high-grade ore shipped direct to smelter, the future output will exceed 450,000 tons per annum. The mine is thus seen to be nearly seven years ahead of mill requirements. The assets, including book-cost of the several mines, are estimated at \$4,689,733. The contributions of the various mines to the ore production were: Sullivan mine, 56,155 tons, Bunker Hill, 270,985; Stewindler, 14,560. The total output of shipping ore was 3570 tons. The costs of stoping in cents per ton were as follows: foremen, bosses, blacksmiths, machinists, tool-packers, and others, 18.5; timbermen and carpenters, 8.2; miners, 34.3; carmen, 6.7; shovelers, 38.6; power-labor, 2.7; repair-labor, 2.6; explosives, 9.4; illuminants, 2.2; lubricants, 0.5; iron and steel, 0.8; miscellaneous supplies, 3.5; timber and lagging, 19.2; power supplies, 3; wood, 4.8; stable and stock, 0.5. This comes to a total of \$1.555 per ton. The total of all ore mined (344,470 tons) was produced at a cost of \$538,363. The concentrator treated 341,700 tons of ore, putting 5.05 tons into 1, at a cost of 38.6c. per ton. The distribution of this cost was: general labor, 4 cents; millmen, 13.6; laborers, 0.9; power-labor, 0.8; crusher-labor, 0.5; repair-labor, 1.3; illuminants, 0.4; lubricants, 0.5; iron and steel, 0.2; miscellaneous supplies, 7.4; lumber, 0.5; roll shells, 0.4; trommel screens, 0.5; crusher supplies, 0.9; power supplies, 4.3; and wood, 2.4. The summary of all costs per ton is as follows: stoping, \$1.563; tramming, 8.3c.; concentrating, 38.2; shipping, 4.7; superintendence and office expense, 8.; contingent expense, 4.1; ordinary legal expense, 0.8. Exploration amounted to 4,844 ft. of drifts, cross-cuts, raises, and winzes, costing \$44,152, or \$9.507 per foot. The average assay of the ore mined was 11.74% lead and 4.33 oz. silver per ton. This gave a gross value of \$3,972,337. The loss in mill-tailing amounted to 18.88% of the lead and 22.09% of the silver, making 19.44% of the combined market value of the lead and silver. The report submitted by Stanly B. Easton, the manager, contains a vast amount of minute detail, worthy the careful study of mine operators.

The company is at present confronting litigation brought by the Federal Mining & Smelting Co., claiming title through alleged apex-rights to portions of the Bunker Hill & Sullivan veins in depth. There is also a claim for damages for ore taken from the disputed ground. The Bunker Hill & Sullivan has expended large sums in investigations made by leading economic geologists in preparation for this legal contest. It is asserted that these studies have proved valuable to the company in the evidence adduced for an indefinitely long life for the mine, and that the light thrown upon the question of ore-genesis has been of the highest practical importance.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—NEGLIGENCE IN STORING EXPLOSIVES.

The negligence of a mine owner in storing dynamite in dangerous quantities, where its accidental explosion would necessarily endanger the lives of the employees, was held to be the approximate cause of injury to a miner by the explosion of the dynamite, though the source of the spark exploding it was accidental and unknown.

Brown v. West Riverside Coal Co., (Iowa) 120 N. W. 732, Apr. '09.

DEED RESERVING MINERALS—EFFECT.

A deed conveying land, but reserving to the grantor all the clay, fire-clay, and other minerals, severs such minerals in ownership from the land, and creates two estates therein; and the grantee, the purchasers of the surface, can not obstruct the mineral owner from the use of the surface for ingress and egress and methods of transportation fairly useful and necessary.

Porter v. Mack Mfg. Co., (W. Va.) 64 S. E. 853, May '09.

MINER—ASSUMPTION OF RISK.

A miner assumes the risks incident to the service, and where the service involves the use of explosives, he takes on himself the risk of all injuries to which he may be exposed by their reasonable use; but he does not assume any risk created by the negligence of the owner of the mine, unless he knows and appreciates, or, as a reasonable person, ought to know and appreciate, the peril arising from the negligence, and chooses to remain in the service.

Brown v. West Riverside Coal Co., (Iowa) 120 N. W. 732, Apr. '09.

OIL AND GAS LEASE—CONSTRUCTION.

The discovery of oil or gas under a lease giving the right of exploration and production, in the absence of anything showing a contrary intention, is sufficient to create a vested estate in the lessee of the exclusive right to produce oil or gas; but the right may be lost by abandonment, by failure to produce oil or gas, or to pursue the work of production or development of the property. But the right will not be lost merely because the lessee continued to drill deeper in search of oil or gas in a lower sand, and oil or gas was not found in such lower sand within the limitation described by the lease.

Eastern Oil Co. v. Coulehan, (W. Va.) 64 S. E. 836, Apr. '09.

LOCATION OF MINE—DECLARATORY STATEMENT.

A declaratory statement describing the development work of a mine read as follows: "At the point of discovery a cut, the dimensions of which are 5 by 11 ft. and 5 ft. in depth, along the course of the vein has been run"; and in an amended declaratory statement it was stated that the locator within 30 days after posting his notice of location did distinctly mark said location upon the ground, so that its boundaries could be readily traced, and did dig a cut at the point of discovery of the following dimensions, to-wit: 5 ft. wide, 15 ft. long, and 10 ft. deep at the face of the cut." And the notice contained another statement as follows: "At the point of discovery said locator and claimant has dug a cut the dimensions of which are 5 by 15 ft. and 10 ft. in depth, in which is disclosed a well defined vein, crevice or deposit of ore at a vertical depth of at least 10 ft. below the lowest point of the rim or collar of said discovered cut at the face of said cut at the surface." Both the original and amended declaratory statements were filed within the required time after the notice of location was posted. While these declaratory statements did not comply technically with the requirements of the statute, the court said there was in them at least a substantial compliance, and that this was all that has ever been required.

Butte Northern Copper Co. v. Radmilovich (Mont.) 101 Pac. 1078, May, '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

STATISTICS OF THE CLAY-WORKING INDUSTRIES IN THE UNITED STATES IN 1908. By Jefferson Middleton. Advance chapter, Mineral Resources of the United States. U. S. Geol. Surv., Pp. 52. Washington, 1909.

FACTS ABOUT THE COEUR D'ALENES. Coeur d'Alene Mine Makers' Association. Pp. 31. Wallace, Idaho.

A general description of the mines of a district that has a record of \$36,501,000 paid in dividends.

IRRIGATION ENGINEERING. By Herbert M. Wilson. 6th ed., revised and enlarged. 8vo., pp. 625, ill., index. John Wiley & Sons, New York, 1909. Price \$4.

Works on irrigation engineering are in great demand, and Mr. Wilson's is one of the most popular on the subject. His descriptions of methods are clear and concise, and the illustrations are copious and helpful. The work is designed for the layman, as well as being useful to the engineer. It is not mathematical, only a few of the problems arising being treated in detail. It is essentially an outline of methods, useful in planning and executing irrigation problems. Descriptions of many important dams, including the Roosevelt dam in Arizona, are given.

SUGGESTED RULES FOR RECOVERING COAL MINES AFTER EXPLOSIONS AND FIRES. By W. E. Garforth. 5 by 7, pp. 71., ill., maps. D. Van Nostrand Co., New York, 1909. Price \$1.50.

This is an exceptionally useful book. It covers an otherwise neglected field, is written by a competent authority, in simple, direct style, and is suggestive rather than dogmatic in tone. It is especially valuable in that much attention is devoted to precautions to be taken before an accident, and if these be followed there is no question that many small accidents may be prevented from becoming large ones. The book is up to date and takes full account of the changes in method of attack made necessary by the introduction of the oxygen helmet. It is bound in flexible covers and is suitable for being carried in the pocket.

LO ZINCO. By Roberto Muso-Boy. 4 by 6. 219 pp., 10 fig., 4 pl. Milano, 1909. Published by Ulrico Holpli. Price \$1.

This is an excellent little hand-book treating of the character and properties of zinc, its mineralogy, metallurgy, production, and uses, with chapters on sheet zinc, zinc alloys, zinc white, and lithophone. The author sticks to essentials and to principles. His account of treatment is not up to American practice and his knowledge of American deposits is naturally quite limited. For general principles, however, and to those who wish some account of the important Italian zinc deposits, the book can be recommended. A list, with addresses, of Italian zinc producers is included.

CONCRETE PLAIN AND REINFORCED. By Frederick W. Taylor and Sanford E. Thompson. 2d. ed., 8vo., pp. 847, ill., plates, diagrams, index. John Wiley & Sons, New York, 1909. Price \$5.

This work has been substantially enlarged in order to keep it abreast with the advance made in modern construction, where concrete is playing a part of ever increasing importance. The chapter on 'Reinforced Concrete Design' has been increased from 51 to 131 pages, and similar copious additions have been made throughout. The statement of results obtained by recent study of failure of concrete beams under diagonal tension will be found particularly interesting. In fact, this volume contains a most useful discussion of the entire subject of concrete beams. The first chapter is entirely new. It deals with the essentials of concrete construction, such as testing materials, proportioning the mixed aggregate, proper strengths for cement and concrete, water-tightness, effect of sea-water, and the like. The present edition brings the total issue in four years up to 11,000 copies.

EDITORIAL.

CONSERVATION work in Hawaii has taken practical form. A special tax has been provided that yields over \$300,000 per year. The larger part of this is being used to promote emigration to the islands of men of the white races with a view to increasing the number of smaller holdings of lands. Topographic maps and stream gauging are being undertaken preparatory to water storage and land reclamation.

EDITAROD, in Alaska, is to be accessible by a new route if present plans carry. The Alaska Northern railroad, the old Alaska Central, is maintaining train service from Seward to Mile 72 from which point it is 400 miles to the new camp. Trails for part of the distance are already available, but appeals have been made to the Alaska Road Commission for a hundred miles of new winter trail, to complete the route. If reports continue favorable the service by this line may be maintained all winter. Stocks of provisions were taken in from Nome and Fairbanks before the close of navigation so that there is not likely to be suffering despite the rush.

THE Geological Society of America will hold its Twenty-Second Annual Meeting at Cambridge and Boston, Massachusetts, December 28 to 30. The Society is evidently enjoying well deserved prosperity. There are twenty-four candidates for Fellowship—a group of brilliant young men, all of whom have made valued contributions to science. It is in the stimulation of such workers that the Society is most useful. Honoring men who have served with distinction is a scarcely less important function. In electing as correspondents Messrs. Charles Barrois, W. C. Brögger, Archibald Geikie, Albrecht Heim, Emanuel Kayser, Edward Suess, and Ferdinand Zirkel, the Society is honoring itself as well as the men selected.

GOLD was produced in the Philippine Islands to the amount of \$78,000 in 1907, \$200,000 in 1908, and to a much larger sum in 1909. Dredging in particular is proving profitable. The dredges in operation are of the New Zealand type and are small. According to the report of the Bureau of Mines, one of them in the Paracale district last year handled 50,244 cubic yards, from which 2814 ounces of gold, worth \$50,653, was recovered. The period of work extended from May 25 to December 31. The placers are shallow and the bedrock a soft decomposed schist. The material is fine, 80 per cent passing through the screens. The black sand is valuable and is being saved for future concentration. This year two more dredges were built in this district. In the Benguet and Masbate districts

quartz mining is attracting attention and the operators are obtaining substantial results. The Mining Bureau is making an effort to attract the attention of American capitalists and miners. Coal of good quality is now available, the labor problem is proving relatively simple, and in general the mining laws are satisfactory. The field would appear to be well worthy of investigation.

TO ALLOW lorries on which the banksmen stand passing over the pit top four balks are often placed across the mouth carrying bridge rails on which the lorry and the bogie into which the kibble empties may be run. No, this is not a code message, neither has it anything to do with the 'Quantitative Classification of Igneous Rocks'. It is not even from Hashimuro Togo, but is English as it is written and printed in England, being an extract from a recently issued text-book on shaft sinking. The book is written by a well educated, thoroughly competent engineer, and excellently printed. The extract will perhaps explain sufficiently why it can never be of more than local use. Americans have no desire to claim a prescriptive right to the English language, but in all fairness we protest against English of the English, if this be a sample, being used in text-books.

PRAISE for the Mexican banking system has often been given in these columns; we believed that it deserved the commendation it had so widely received; but there is a weak point in every structure. There is a weakness in the Mexican banking law which needs the attention of the legislative body of the Republic. The Compañia de Hornos Partridge, S. A., is being re-organized with a capital of \$1,000,000 as the Banco Refaccionario de Fundiciones de Minerales, under the law providing for mortgage banks. These correspond in some respect to what are known in this country as State banks, to which are usually accorded the right of advancing money on real estate. This privilege is seldom exercised by the stronger State banks, which prefer to do business along safer lines, with funds readily available from commercial paper on short-time loans. But the debasement of banking to the level of a selling agent for special manufactures has never been sanctioned, tacitly or otherwise, in the United States, whatever other defects may have been permitted. In most States such practices are constituted misdemeanors, or felonies. The Banco Refaccionario de Fundiciones de Minerales, proposes, in the words of Mr. J. J. Mendez, its president, "to push our smelting system in those mines which have sufficient tonnage for treatment, but which have not capital enough to proceed with development." We know nothing of the merits of the Partridge smelting system; but we do know that there is something wrong with the Mexican banking law if it can be used to promote a special industry, diverting the capital of a bank and the money of its depositors, to subserve such an end. If this can be done by one concern, it must be so utilized by others, and the expectation of Minister José Yves Limantour to create general confidence in the credit system, which is vital to the industrial expansion of the country, must shortly experience a rude shock.

Encouragement to Shipping.

A certain humor lies in the fact that advocates of a Government-fostered merchant marine shy at the very shadow of the term 'subsidy'. Subsidy means 'lying in wait', and was applied to reserve forces in the Roman army, waiting ready to render aid in time of battle-stress. The public, however, all unconscious of etymologic bearings, has acquired the conception of somebody lying in wait when a subsidy is proposed, and it is difficult to eradicate the impression of things sinister from the word. Therefore, since it is to cast reproach if we use the word subsidy, let us speak in seriousness of the need to do something by way of encouragement to American shipping.

It was our privilege some time ago to point out the value of a large merchant fleet in attracting metallic products to our shores, and the consequent stimulus this would give to smelting. America is now the greatest producer of copper and lead in the world, which metals constitute the basis of the bulk of the smelting industry. Whereas in the early days the metallic output of this country was nearly nil, it is well to remember that the Baltimore clipper service carrying Yankee notions to Chile resulted in bringing back regulus, mattes, and copper bottoms, which were refined on the Patapsco. Thus was built up a copper business at Baltimore which all the subsequent changes in place and amount of production have been unable to destroy. The Baltimore refinery draws copper today from Montana, Utah, Colorado, and Arizona. A great shipping would give rise to many seaboard refineries, and render control of the smelting industry by a monopoly even more difficult than it is today. The exports of metal from South America are growing rapidly, and the United States should be prepared to draw them to her ports. The opinions expressed in our columns were voiced as a resolution by the American Mining Congress at Goldfield in September. To this Mr. Francis G. Newlands replies in another column, following the line of argument laid down in his speeches elsewhere, condemning the principle of a direct subvention, but urging the construction of vessels by the Government to serve in time of war as transports and colliers, and in times of peace as merchant vessels, operated under lease to private parties. This suggestion bears a family resemblance to the plan carried out in some other countries where loans are made by the government to private ship-owners, the ostensible object or excusing warrant being the provision of available carriers for national use. The suggestion is interesting; as a supplement to other measures it might be worth trying; but it seems utterly inadequate as a means for sending the American flag (as we love to say) proudly flying into all the ports of the world. The Merchant Marine League of California, which was organized the other day, with Mr. Frank B. Anderson as president, is making an earnest propaganda in favor of the Humphrey bill (H. R. 2694), calling for a mail subsidy of \$4 per mile on outward voyages of 4000 miles for vessels of 16-knot speed, on routes to South America, the Philippines, Japan, China, and Australia. This would be merely a sop; its importance would be mainly in establishing a precedent for a really effective law to stimulate

shipping under the American flag. As such it is worth working for. Certain it is no hope exists for an American shipping while our present tariff schedule remains in force, unless the ship-owners receive protection as well as the manufacturers. As a guarantee for adequate return to the public for such out-go, Mr. Champ Clark might propose his support and that of his followers in exchange for a bill preventing railroad discrimination in aid of any particular ocean carriers. When all steamship companies may automatically enjoy the advantages accorded the ones most favored by the railroads, abuse of ship subsidies is not to be feared.

Bullion-Tax Law in Nevada.

The poor man pays his taxes and grumbles; the rich man usually dodges all the taxes he can and protests. The more conservative and permanent an industry, the more readily does it submit to the tax assessor; the more speculative the business, the less is it willing to divide with the State which gives it protection. When Nevada was poor and its population small, the miners could have repealed the so-called bullion-tax law, but they accepted it as one of the inevitable conditions of life, along with poverty and hopes deferred. In fact, there was so little metal of any kind produced that few Nevadans were really conscious of the existence of such a law; they seldom came within range of its operation. Now that Nevada is rich and prospering, with mammoth copper mines at Ely, with gold and silver mines producing at Goldfield, Tonopah, and Silver Peak, and with the Comstock showing signs of revival, the mineral-tax law becomes a matter of great importance. When the mining law of 1866 was introduced in the Senate by John Sherman, he contemplated not only the disposal of the mineral lands, but permanent revenue to the Government from the minerals in the form of royalty. It was as a fiscal measure that the bill was drawn. The profound change from a law for revenue to one for encouragement of mining by granting title to mineral-bearing claims was effected by William M. Stewart, of Nevada, and yet the State he represented presently applied to its own benefit the principle advocated by Mr. Sherman. The law is an old one, and hence will not readily be erased from the statute books. The questions of the moment relate to the application of the law, or, stated otherwise, to its legal evasion. The burden rests upon "ores, tailings, borax, soda, or mineral-bearing material." The tax is assessed upon the net proceeds, which are subject to the same rate of taxation, *ad valorem*, as other property. The actual cost of extracting the ore or mineral, cost of selling, or cost of reduction and sale of the refined product, may be deducted, to arrive at the net proceed. This seems simple, although questions of theory in accounting enter into what may constitute legitimate charges against the gross output. A battle is being fought around the principle of depreciation. The recognition of this charge is readily admitted in the case of a custom plant, but is contested when applied to a mine, whether or not it be equipped with reduction works. It is somewhat difficult to see justifica-

tion for such a distinction. Theoretically a custom works would be available for all who might choose to ship ore to it for reduction; its zone of attraction would presumably include a larger and more enduring source of ore supply than a single mine would normally afford. Consequently the charges for repairs and renewals should cover depreciation to so large an extent that the chief contingency against which a depreciation charge would provide would be that of a possible change in current practice or methods of reduction which would render the plant obsolete. This contingency is always important in metallurgical operations. The depreciation charge is necessary in consequence. It is merely insurance against extinction, or against the possible necessity for seeking additional capital.

In the case of a mine, if conservatively financed, the capital would be returned within the predicted life of the enterprise, together with suitable profits. When exhausted, liquidation and dissolution of the corporation would follow. The conception of a mining company as ephemeral has widely prevailed, but in many parts of the world today such corporations are taking measures to prolong their existence by purchasing and operating new properties. There is no reason why this should not be as legitimate an aim for a mining company as for manufacturing concerns which fall under the classification of 'industrials'. A manufacturing company usually does not depend upon a single source of raw material. It draws from the cheapest source, and its relations to supply and market are changing. In order to prepare against eventualities, a depreciation or amortization charge is made, which is deducted from gross profit before distribution of dividends. We fail to see why such provision for the future is not as commendable in the case of mines as in that of manufactures. Tax assessors in Nevada do not see it so, and the law makes no specific mention of depreciation as a legitimate deduction from the net value of the output of a mine, but warrant is found for admitting its validity in the case of a reduction works. The two seem so analogous that it would appear warrantable to revise the statute in order to spare the world the unpleasant spectacle of corporations evading one law by taking shelter under another. What is permissible under certain statutes can not be wrong because not sanctioned under a specific statute. There is a fine sense of regard for the law, as interpreted by the officials, in the act of the Nevada Consolidated, which controls its reduction plant under a corporation separate from that which owns the mines. It writes off nothing for depreciation on plant, but charges the actual cost of treatment against the ore in the returns made to the tax assessor. On the other hand, the Goldfield Consolidated has made over its railroad and mills to a subsidiary corporation known as the Goldfield Consolidated Milling & Transportation Company, in order to avoid an excessive bullion-tax. Stock of the new company is owned absolutely by the Goldfield Consolidated Mines Company. It is an evasion, pure and simple, but frankly done, and should serve the purpose of awakening the Nevada legislature to the necessity for enacting a remedial measure.

PUMPING AND SHIPPING OIL IN EASTERN ILLINOIS.

Written for the MINING AND SCIENTIFIC PRESS
By R. S. BLATCHLEY.

After a well has been shot it is cleaned and tubing is put in to the bottom. The tubing is 2 in. diam. and costs $11\frac{1}{2}c.$ per foot. Inside of the tubing is put a 5.8-in. sucker rod extending to the bottom of the well. If the well is the initial one, the rod is attached direct to the walking beam of the drilling engine and is set to pumping. The well is connected to a nearby tank where the oil is caught or it is sent to the gen-

Producers Tank.

eral lease tanks. The tanks are cylindrical, being built of wooden staves, and are generally gauged to hold 250 bbl. Some range up to 1600 bbl. capacity. In the 250-bbl. tanks, each inch in depth equals $2\frac{1}{2}$ bbl. of oil and 'ten inches of oil', to use the terms of the oil man, equals 25 bbl. The cost of 250-bbl. tanks is about \$95. Second-hand tanks cost almost the same, and are more in demand, as it is considered that they are better, having already absorbed their quota of oil. Where there are a number of tanks on a lease a shed is built over them to protect the oil from evaporation by the sun. The tank-houses cost about \$60.

If a number of wells are drilled, a power-house is placed as near as possible to the centre of the lease. A gas-engine is installed usually on a concrete foundation. From the power, the wells are pumped by means of steel pull-rods or wire ropes provided with suitable angle-knees to change the direction of the pull. The rods are attached to an oscillating pull-wheel and are thus given a horizontal movement. At each well there is erected a 'jack' and a balance weight, to which the necessary sucker rods, which ply up and down inside the tubing, are attached. The weight of the sucker rod pulls the surface rods one way, while the pull-wheel pulls them the other way, thus giving the necessary balance of work. The surface rods are placed as nearly as possible on a level line and are guided by being set in notches cut in the top of short posts or props. The friction of the rod and the post is eliminated by keeping the con-

tact greased occasionally with common axle grease. One power will, at full duty, pump as high as 40 wells, but it is thought best not to put more than 25 or 30 on one power. The power man in charge can not look after any more than this and do his work well. To make the rounds of the wells twice a day will occupy most of his time. To this must be added looking after the engine and tanks, and making reports. The fuel used for pumping is gas, and is generally piped from the wells on the lease. There is occasionally a lease without gas, and in that case it is bought from some other lease or from a pipe-line.

The oil is pumped from the wells into the lease tanks and the salt-water present finds its way to the bottom of the tank, where it is drawn off by siphon or by plug. In pumping, the oil often roiles and a sediment arises which can not be piped with the oil. This is piped away from the bottom of the tank to a pit some distance from the power. The waste is burned and not allowed to run into the streams. In fact, a recent investigation by Federal authorities has put a stop to running waste oil into streams, it having killed many fish in the Wabash river.

After a tank has been filled it is customary to run steam through the oil to settle the sediment and impurities. This is done by running steam-pipes to the bottom of the tank. About three hours is necessary to steam a tank of 250-bbl. capacity. After this is done the oil is ready for the market. The power man notifies the Ohio Oil Co.'s gauger, who visits the lease on his rounds and measures the oil. A report

Stoy Station of Ohio Oil Company.

is made up and is signed by the gauger and the power man. In the report the amount of the oil is given and the method of conveying it—whether or not it is pumped or sent down a gravity line. In all reports 3% of the oil as gauged is deducted to allow for leakage, sediment, and evaporation. During the last two years the Ohio Oil Co. has built an extensive system of gravity gathering lines eliminating the cost of pumping oil from each lease. They have taken advantage of the slope along the streams and have placed pipe-lines along them, with branch lines to each lease. The oil flows down the line to a central sub-station, where it is caught and pumped back

through a large main to the pumping stations proper, situated at Bridgeport, Stoy, and Martinsville. From the latter point it is pumped through one 12-in. and two 8-in. pipe-lines across Indiana and Ohio to Eastern refineries, and one 8-in. line to Alton, on the Mississippi river. It is estimated that the discharge of oil from the lease tanks by gravity is twice as fast as through the use of the donkey pumps. A pump was previously requisite on each lease. It cost about 1c. per barrel to pump it in this fashion, whereas by the use of gravity it costs about 1/3c. In all cases the Ohio Oil Co. pays for the transfer. A regular force of men, aside from the company's corps of surveyors, is kept at work the year around, improving and repairing the lines. Today practically every lease in the field is provided with its branch gravity line, which runs to the nearest creek, while the company is keeping pace with new development, by laying new lines.

The development of the field and the production of oil has so increased beyond the ability of the Ohio Oil Co. to take the supply that a system of storage tanks has been established in conjunction with the

company's storage tanks. Accurate record is kept of the oil in these tanks by the auditing department, and when the oil is ready to be run eastward it is turned over to the discharge department. This division merely regulates and checks the pumping of the oil into and through the interstate lines.

In case the tank is struck by lightning and set afire, the company saves as much of the product as possible, about one-half usually, and the operator is not held responsible for any loss. It has been stated before that in gauging 3% of the oil was deducted for evaporation, and the like. The evaporation takes place during the storage of the oil in the steel tanks and in the transportation. Loss also occurs through sedimentation. The volatile portions of the oil are continually escaping. The Ohio Oil Co. is not a common carrier of oil, but is a buyer. The old system of merely carrying the oil and charging a certain sum for storage have nearly disappeared. The auditing department of the oil company is one of the most complete systems of its kind in existence, and the daily work it takes care of, as well as the keeping up of weekly and monthly reports, is enormous. The

Loading Rack for Oil.

discharge of gravity lines. Permanent tank-farms are maintained at Martinsville, Stoy, and Bridgeport. To these points, the central sub-stations discharge the oil for storage until it can be pumped eastward. Up to September 1, 1909, the Ohio Oil Co. had 480 of these tanks, each one having a capacity of 37,500 bbl. The cost of each tank, including the making of a circular dike to catch the oil in case of the bursting of the tank or of a fire, is \$9000. The tanks are made of riveted iron plate 1/2 in. thick at the bottom and 3/16 in. at the top. They are 95 ft. diam. and 28 ft. 7 1/2 in. high. The actual floor space is 7200 sq. ft. Some of the larger companies operating in the field have also established tanks for their own storage.

Each oil operator has his oil gauged and run. A 'run ticket' is made out and signed and the record is sent in to the Ohio Oil Co.'s books. In the course of one or two days checks are made out individually to the operators and to the farm owner, on the basis of a 'division order' signed and placed on file by all parties to each lease. The gauger is the agent standing between the people and the pipe-line company. He is paid good wages and is chosen for honesty and impartial work. After the oil is let into the gravity line it is considered bought. It is sent down the line to the sub-station, and in turn is sent to one of the

system is so complete that complaints hardly ever arise from the operators or from the land owners. The Ohio Oil Co. is taking about 60% of the production at the present time, or about 80,000 bbl. per day. Of this amount they are pumping about 71,000 bbl. eastward. They have at one time pumped the full capacity of 102,000 bbl. per day, but this rate could not be maintained. At the present time practically all the lease and storage tanks are kept full, and drilling and new development is discouraged. The average price per barrel in 1906 was 74c. In 1907 it dropped to 67.7c., and in 1908 to 67.2c. This last summer brought another drop

of price and a grading of the oil. In the spring, the price was 65c. for oil above, and 57c. below 30°. Later in the summer it declined to 60 and 52c. The latter prices prevail at the present time. Illinois ranks third in the production of petroleum, Oklahoma and California being first and second. The following table gives the monthly runs of oil from the years 1905 to 1908, as compiled by the Illinois and Federal Surveys:

| PRODUCTION OF OIL FROM 1905 TO 1908. | | | | |
|--------------------------------------|---------------|---------------|---------------|---------------|
| Month. | 1905, bbl. | 1906, bbl. | 1907, bbl. | 1908, bbl. |
| January | 55,680 | 781,812 | 2,640,065 | |
| February | 65,209 | 956,399 | 2,607,620 | |
| March | 19,352 | 1,547,232 | 2,734,617 | |
| April | 102,862 | 1,874,465 | 3,232,123 | |
| May | 267,746 | 1,138,918 | 3,227,522 | |
| June | 5,489 | 410,654 | 1,879,362 | 3,108,492 |
| July | 9,208 | 610,401 | 2,422,192 | 2,722,683 |
| August | 15,092 | 778,463 | 5,446,042 | 2,833,637 |
| September ... | 19,591 | 722,168 | 2,605,663 | 2,698,577 |
| October | 26,443 | 463,819 | 2,863,812 | 2,725,267 |
| November ... | 34,766 | 350,985 | 2,510,146 | 2,499,092 |
| December | 45,913 | 549,711 | 2,255,839 | 2,655,411 |
| Total | 156,205 | 4,397,050 | 24,281,973 | 33,685,106 |

The grand total of oil produced up to January 1, 1909, was 62,520,631 bbl. This did not include the

oil stored at that time, but gives the actual runs. It does include, however, the oil shipped by tank lines to minor refineries near the oilfield. Loading racks are kept up for tank-lines at Bridgeport on the Baltimore & Ohio railroad; Lawrenceville, Flat Rock, and Robinson, on the Big Four railroad; Bakers Lane, Oblong, Stoy, and Robinson, on the Indianapolis Southern railroad; Casey and Martinsville, on the Vandalia railroad; and Casey and Westfield, on the Cincinnati, Hamilton & Dayton railroad. Annual tank shipment amount to about one and one-half million barrels.

The average cost of the first well for the different pools and to the various sands in 1909 is as follows:

| COST OF INITIAL WELL. | | | | | | |
|--|------------------|---------------------|---------------------|-------------------|-------------------|----------------|
| | Clark county. | Crawford county. | Bridgeport Sand. | Buchanan Sand. | Kirkwood Sand. | Tracy Sand. |
| Rig | \$500 | \$500 | \$500 | \$500 | \$500 | \$500 |
| Drilling | \$360 | 800 | 875 | 1750 | 2200 | 2600 |
| Drive-pipe | 80 | 90 | 90 | 800 | 550 | 1200 |
| Casing | 250 | 650 | 700 | 1440 | 1550 | 2000 |
| Shooting | 90 | 90 | 90 | 100 | 100 | 100 |
| Tubing and pumping out- fit | 150 | 150 | 150 | 200 | 215 | 250 |
| Power and power-house with boiler | 1200 | 1200 | 1200 | 1200 | 1200 | 1200 |
| Two tanks and tank- house | 250 | 250 | 250 | 250 | 250 | 250 |
| Belting and lead-lines... | 100 | 100 | 100 | 100 | 100 | 100 |
| Incidentals | 100 | 100 | 100 | 100 | 100 | 100 |
| Totals | \$2580 | \$3930 | \$4055 | \$6440 | \$7765 | \$8300 |

Following are the average depths of the various sands:

| Sands. | Feet. |
|------------------|--------------|
| Shallow | 400 to 500 |
| Robinson | 800 to 950 |
| Bridgeport | 950 to 1000 |
| Buchanan | 1320 to 1360 |
| Kirkwood | 1400 to 1550 |
| Tracy | 1750 to 1800 |

The average amounts of drive-pipe, casing, tubing, and rodding are given below for the different sands:

| Sands. | Drive-pipe. | | | Casing. | | | Tubing. | Rodding. |
|------------------|-------------|------------|--------|-----------|-----------|------------|---------|----------|
| | 13 in. | 12 1/2 in. | 10 in. | 8 1/4 in. | 6 1/4 in. | 5 1/16 in. | | |
| Shallow | .. | .. | 90 | 1130 | 1450 | 1700 | 440 | 440 |
| Robinson | .. | .. | 90 | 150 | 300 | .. | 890 | 890 |
| Bridgeport | .. | .. | 100 | 400 | 900 | .. | 940 | 940 |
| Buchanan | .. | .. | 820 | 400 | 950 | .. | 1340 | 1330 |
| Kirkwood | 40 | .. | 450 | 1300 | 1350 | .. | 1450 | 1450 |
| Tracy | .. | 350 | 720 | 1100 | 1460 | .. | 1760 | 1760 |

The cost of casing is as follows: 10-in., \$1.05 per foot; 8 1/4-in., 70c.; 6 1/4-in., 39c., tubing, 11 1/2c.; rodding, 4 1/4c. The incidentals, given in the above table include the cost of teaming, which averages \$4.50 per day in Clark and Lawrence counties and \$5 per day in Crawford county, and the expenses of the operator, such as livery, etc. The second and succeeding wells on a lease cost about \$1500 less in the Shallow fields, \$1850 in the Crawford county pools, \$1900 for the Bridgeport sand, \$2600 for the Buchanan sand, \$2600 for the Kirkwood sand, and \$3000 less for the Tracy sand, as the rigs, drive-pipe, a part of the casing, tanks, power, and power-house can be used repeatedly. There is, of course, an expenditure for tanks, engine fittings, and supplies, in addition to the above items. The cost of lead-lines and sur-

face-rods on a lease will increase proportionately with the number of producing wells.

The cost of operating a lease after it has become productive averages about \$136 per month. Of this, \$66 is for the salary of the pumper, \$40 for fuel, and \$30 for teaming and supplies. The supplies include cups, packing, tools, etc. This estimate applies to a lease of 10 wells. However, 15 to 20 wells can be operated almost as cheaply as 10. Generally if there are more than 12 wells a helper will have to be employed. He is termed the 'roust-a-bout'. It is found to pay to pump three or four wells on a lease, even if the yield is only 5 bbl. each per day. This is considered the lowest payable yield in the field. The output from four 5-bbl. wells per month, after deducting the royalty of one-sixth, is 500 barrels.

At the current price of 62c. per bbl. the following table can be made:

| | |
|---------------------------|-------|
| Income per month— | |
| 500 bbl. at 62c..... | \$310 |
| Salary of the pumper..... | \$66 |
| Cost of the fuel..... | 40 |
| Cost of supplies..... | 30 |
| | 136 |
| Net income | \$174 |

The opening of the Illinois field brought an influx of men eager to invest, who found that the field was already leased and taken. They discovered that the only way to become interested was to organize a company and buy properties that had already been found to be productive. Sometimes they attempted to buy up what stock was in the market. This was usually found to be scarce and many investors found hardly any opening. It is true that the oil faker has not set foot to any extent, if at all, in the main oilfield, as it is too thoroughly studied and known. The operators are closely allied, and it is thoroughly understood that dishonest men are not wanted. Nor can he find a chance to operate near the field, because of the vigilance of the men old in the business, who watch all new drilling. There has been some 'salting' of wells in the outlying territory in the State, but in every case the faker has been exposed.

It is common advice to every one that it is not safe to invest in any oil venture unless he is well acquainted with the promoters of a company and knows them to be honest and experienced oil operators. If it is desired to speculate, then it is proper to investigate personally. The oil business is a gamble itself, that is, risk is always present and chance is a big element in success. Careful study may, however, eliminate some of the chances of failure.

It is fortunate that the Federal Survey found opportunity to carry on topographic surveys in and about the Illinois fields. Work is being done at present in the Bridgeport quadrangle, and in 1908 the Hardinsville quadrangle was completed to the north of it. This gave an opportunity to the State Survey to run levels to about 5000 wells. By this means the dip of the sands is being definitely plotted and contour lines are being drawn. This is done by subtracting from the elevation above sea-level of each well that of the top of the oil-sand below. Relations to the anticlinal features present are being studied, and it is hoped that a report of value in finding oil properties will result.

EXPLOSIVES IN THE UNITED STATES DURING THE LAST THREE YEARS.

By CHARLES E. MUNROE.

*In my report on the progress of the explosives industry in the United States, made at Rome, I was obliged to give an estimate for the quantity of explosives manufactured in this country in 1904. Since the Congress at Rome was held, analysis of the data of the Census of Manufacturers of 1905, which practically covered the manufacturing operations of the calendar year 1904, has been completed, and a detailed account of the results, together with those obtained through a similar census in 1900, are presented in the accompanying table. These statistics show an increase in every item for 1905, as compared with 1900, the largest increase in value, \$4,652,970, being for dynamite and, except for 'all other explosives', the largest percentage of increase in value, 156.8%, is for smokeless powder. The largest increase in quantity, 86,062,500 lb., is shown for blasting powder, and the next largest, 45,074,373, for dynamite, but the greatest percentage of increase in quantity, 129.6%, is for smokeless powder. The quantities and cost of the principal materials used in the United States during the census year 1900 and 1905 are set forth in Table II.

The statistics of Table II also show an increase in every item, the largest increase in quantity, 53,002 short tons, being in mixed acids; the second largest, 44,510 short tons, being in nitrate of soda; and the third largest, 18,504 short tons, being in charcoal. The largest increase in any single item of cost, \$2,705,691, is for nitrate of soda; the second largest, \$1,307,663, for mixed acids; and the third largest, \$1,113,108, for glycerine. Pyrite appears among the materials used in this industry for the first time in the census of 1905, and it marks the introduction in the United States of contact-processes for the manufacture of sulphuric acid, a material which is extensively consumed in the manufacture of explosives. The marked increase in the quantity of nitrate of ammonia used, 3,202,058 lb., or 539.1%, indicates the marked increase in the quantity both of safety-explosives manufactured, and of weak nitric acid residues utilized. It is to be noted that in some instances sulphate of ammonia was employed in place of aqua ammonia, or ammonia liquor, mentioned in Table II. The increase in the quantity of ether used, 2,167,341 lb., most of which was consumed in the establishments in which it was produced, corresponds closely with the increases in the production of smokeless powder and particularly that portion of it which was used in the manufacture of military powders.

The quantity of explosives reported as produced for sale in the census year 1905 was 363,748,097 lb. The estimate given for that year in my report at Rome was 346,841,891 lb., but, as is frequently the case, the estimate was below the truth. Owing to the business depression beginning in 1907 it is not believed that the increase in the output of this in-

dustry for the period subsequent to 1904 has been at the rate shown for the 1900 to 1905 interval, yet this industry has suffered during the period of financial depression less than many other industries owing to the great quantities of explosives required by the United States Government in its large engineering projects at Panama, and in the development of irrigation in the arid regions of the Western States.

In my report at Rome I called attention to the fact that, owing to the geographical situation of our explosives factories with regard to the industries of this country in which their product was consumed, practically all of the product, except such liquid nitroglycerine as was used in removing obstructions in petroleum oil wells, was transported from the factories to the place of use by railroads, and an attempt was made to show the magnitude of this daily transportation, but, through some cause not understood, the figures, as published, were confused, and it may therefore seem proper, since the more reliable data are at hand in place of the estimates then available, to re-state this. In the United States a carload is generally fixed at 20,000 lb., hence, omitting the weight of the containers, the 363,748,097 lb. of explosive produced during the census year 1905 would provide 18,187 carload lots, or for 300 working days per year, there would be supplied 61 full carloads each day. But it is the opinion of railroad officials, based on their experience in transporting explosives, that through re-shipment from central depositories, and from magazines to consumers, the number of cars carrying small lots is five times as great as those carrying full loads, hence the total number of cars loaded with explosives during the year would be 109,122 or 364 per day for a work-year of 300 days. It is further estimated that the average time for transporting each of these cars from the place of loading to that of discharge is 10 days. There will therefore be on an average 3640 cars loaded with explosives on our railroads during each of the 300 days, or for the calendar year, of 365 days, there would be 2990 cars per day, but, as the demand is not constant, the number per day during the busy season would be greater, and near distributing points this traffic would be quite dense. As stated, this estimate is based on the returns for the census of 1905, and while no doubt the traffic has increased within the United States since 1905 at the rate which obtained between 1900 and 1905, first, because of the business depression which has arrested industrial development, and, second, because the factories situated near deep water have been able to ship the large quantities of explosives required on the Panama Canal work directly by water.

Following the consideration by the American Railway Association of methods for controlling the transportation of explosives, an organization was formed styled 'The Bureau for the Safe Transportation of Explosives and Other Dangerous Articles', with Charles B. Dudley as president, and B. W. Dunn chief inspector. This is a purely private organization of railroads formed to secure uniformity in regulations in the different States, it not having

*Read at the Seventh International Congress of Applied Chemistry, London.

been possible to secure this result by legislation. Two annual reports have now been issued by the chief inspector. From the one for the present year it appears that 158 different companies, representing published book of instructions contains an ingenious intersection table which shows at a glance the incompatibles which should not be loaded or stored together. Other pamphlets in which methods of

*'Chemicals and Allied Products', by Charles E. Munroe.

formulated and published by the American Railway Association and cover in detail the packing, reception, handling, stowage, and classification of the various explosive and inflammable substances. The entered upon and the president, chief inspector, and agents have repeatedly addressed bodies of railway men and business men, both managers and employees, in an endeavor to have the properties of

the bodies dealt with and the reasons for the regulations formulated, well understood, so that intelligent co-operation could be secured.

This movement to protect life and property has been facilitated by the Congress, which by Act of May 30, 1908, repealed all previous Acts relative to this subject except Section 4422 of the Revised Statutes of the United States, and it directed the Interstate Commerce Commission to formulate regulations for the safe transportation of explosives, which regulations should be binding upon all common carriers transporting explosives by land, and it fixed penalties for the violation of these regulations. The report of the hearings before the Committee on Interstate and Foreign Commerce through which this legislation was secured is given in House Report 7557 for 1908, and it shows that the officials of the Bureau were largely instrumental in securing this legislation, which brought the regulations of the Federal Government, which controlled between the States, and the Bureau, which operated also within the States, into harmony. An incidental, though important feature of this legislation, was the repeal of the Act of Congress of July 3, 1866, which forbade the transportation of nitroglycerine or similar substances, even when absorbed in a dope, unless they were "securely inclosed, deposited, or packed in a metallic vessel surrounded by plaster of paris, or other material that will be non-explosive when saturated with such oil or substance." This legislation followed shortly after the explosions at New York, Aspinwall, and San Francisco, and the serious accidents accompanying the introduction of nitroglycerine into Europe. It was conceived in fear, and framed in ignorance of the properties of the substances sought to be controlled. The result was vicious because it created a more dangerous set of conditions than obtain in ordinary practice, yet it remained on the statute books of the United States for nearly 42 years. It is safe to say that it never was obeyed, and that the millions of pounds of explosives transported in those years have been transported in violation of law. Singularly, it appears that its violation has never been made a cause of action in the courts until, subsequent to its repeal, it has been brought forward in an issue then on trial. Acting under its general powers to fix railroad rates for transportation, the Interstate Commerce Commission has also differentiated between explosive compounds, and after investigation has by order of April 13, 1908, fixed the rate for an ammonium nitrate composition at second class in carload lots with a minimum of 20,000 lb. and $1\frac{1}{2}$ times the first-class rate in less than carload lots. This was less than was asked for by the manufacturer, but it gives such an explosive great advantages over its competitors. It is the first instance of this kind, and marks radical departure.

Another departure from the governmental methods which have heretofore prevailed is found in the investigation of explosives for use in coal mines and of the causes of accidents in such mines by the United States Geological Survey. This investigation was begun at the George Washington University in 1907, the work there being largely confined to the develop-

ment of methods for the analysis of explosive substances and the test of these as they were found in use in various mines. One immediate result was the drawing up of specifications for explosives to be purchased for use at Panama and in the Reclamation Service, and this system of purchase, subject to chemical inspection, now obtains under the Federal Government. In 1908 a portion of the buildings and grounds of the United States Arsenal at Pittsburg, Pennsylvania, were obtained for the purposes of this research, and an experimental gallery was erected there, testing apparatus of various kinds was installed, a chemical laboratory equipped, and the Station opened for work in September 1908, the occasion being graced by the presence of a board of foreign experts, composed of men who had been engaged in similar studies in Europe. Since then the Station has been steadily employed in making firing trials of analyzed explosives, and in January 1909 the Director of the Survey announced that it was ready to make official tests for permissibility for use in mines containing gas alone, gas and dust, or dust in dangerous quantities, and he announced the test requirements which had been fixed for explosives for use in coal mining. It should be stated that the decisions arrived at can have no other force in law in the States than that of an expert opinion, but the Federal Government may make these decisions law in the Territories and the District of Columbia. It is, however, expected that the conclusions of this Bureau of the Government, and the conditions it fixes, may, through the force of public opinion, come to be accepted as authoritative throughout the different States of the Union.

Since the last meeting of this Congress one of the two smokeless powder factories then referred to as being under the direction of the Navy Department has been dismantled and abandoned, but the other has been greatly developed, while an additional one, of similar magnitude, has been created under the direction of the War Department. This movement has been promoted by the fact that the manufacture of military smokeless powder by private establishments in this country is today controlled by a single corporation, and it is regarded as a sound policy that the Federal Government should possess factories of such capacity, both in time of peace and in time of war, as to prevent a private monopoly from controlling the price of powder when an emergency, in which a considerable quantity is required, arises. A joint board of officers of the Army and Navy has been created for the purpose of determining the composition, methods of manufacture, and sizes of grain, which shall be adopted, so that the product may be interchangeable between the two services according to the calibres made use of. In all this the Navy has taken the initiative, as its factory and methods have been long established, while the Army has but recently become a producer. In common with many European countries the United States has adopted for its service-powder one made only of cellulose nitrate of low nitration, and in common with such other services it has suffered severely from flare-backs, due to the excessive production of carbon monoxide from the incompletely nitrated cellu-

lose, and also from progressive deterioration in storage, which is characteristic of these powders. To ensure stability, provision is made for re-working the powder every three years, and the process has been now so developed that this is done at a cost of but 11c. per pound. Nevertheless, a system of magazine refrigeration is urged on the ground that it will treble the life of the powder, and also better preserve its ballistic qualities.

Among the many new compositions for smokeless powders which have been brought forward, only one seems to have received serious consideration. This one, composed of cellulose nitrate and trinitroanisol, is known as stabilite, and is claimed to possess several advantageous qualities, not the least of which is that long continued drying for the removal of solvents, such as is essential in the manufacture of the cellulose nitrate and cellulose nitrate-glycerol nitrate powders, is unnecessary in making this. There is consequently effected in this feature of manufacture not only a saving of time, but of expense and interest, while the hazard of manufacture is also reduced. However, as it is understood that trinitroanisol may be hydrolyzed to picric acid and methyl alcohol, there is some question as to the permanency of the product, and its suitability for adoption as a service powder, even if its ballistic qualities should be found to be what is desired.

Some of the private arms and ammunition factories engaged in the manufacture of small arms and ammunition for military as well as sporting purposes have come to recognize the value of applied science in fixing the quality of their products. The application of mechanical tests to the metals used has been the practice for some time, but more recently the service of the chemist has been sought with most gratifying results. At the factory of the Winchester Repeating Arms Co., there is expended daily in the firing tests of the ammunition, and of the guns for accuracy and action, 27,000 metallic cartridges, 5200 shot shell cartridges, and 1700 primers. The priming mixtures in these latter are analyzed and tested on a drop-test machine. These tests are very rigid, and but a slight tolerance is allowed. The following is abstracted from a private communication: "In regard to the every day shop-routine tests of ammunition, every powder as it is received by us has its own ballistics determined and its load fixed according to the velocities and pressures which we desire our ammunition to have. Also we take hourly from each machine ammunition, which is in turn tested to see whether we are actually getting the ballistic results that we have ordered from the loading-room. Rifle cartridges are also tested for accuracy and penetration by skilled shooters, who also take notice of any small peculiarities which may show themselves, and the shot shell ammunition is tested for pattern. All powders received by us are unloaded and opened at our powder-receiving house, three miles from the factory, in a large enclosure in which we have our magazines for storage. These magazines are kept under careful observation as to temperature and moisture, and the various powders are tested from time to time for any chemical deterioration. All powders received, of

every description, are subjected to the standard Abel-tests, and the German or 135° test for stability, in addition to the standard stability-tests, and as our ammunition is shipped to all parts of the world, in making our choice as to the acceptability of the various powders, they are tested to see how they will withstand severe conditions of climate. The ammunition is subjected to temperatures from 60 to 150°F., and the effect of these temperatures for different times is noted. We carefully investigate as to the chemical composition, the kind and degree of nitration, and the gun cottons employed in making the powder; the solubilities of the gun cottons; and the hygroscopic properties of the powder. In investigating the ballistic properties of the powder our conclusions are all based on results obtained when the powders are bone-dry; and when they contain a certain given amount of moisture, which we have fixed as one which would be about the maximum the powder would tend to take up under severe conditions; and also after any deterring agent, such as vaseline, has been removed.

The records of the United States Patent Office show that the efforts of inventors during the last three years have been directed largely toward the perfecting of chlorate powders, and the stabilizing of nitro-starch, there having been issued to one inventor on January 7, 1908, 16 patents on the use of various chemical substances in rendering nitro-starch permanent. Nevertheless, neither of these types of explosives appear as yet to have made much progress in use. Among odd stabilizing agents which have been proposed for use are boric acid, borax, and arsenates. A novel chlorate mixture is one containing nitrated phthalic acid.

The advances on the manufacturing side of the explosives art in this country have been largely in the mechanical devices employed, through which the speed of production has been increased, and the cost of the product lessened. Among these may be mentioned improvements in nitrating-centrifugals, whereby the quantity of acid per unit of cotton has been decreased; improvements in hydraulic presses; in powder-cutting devices; in solvent-recovery apparatus; and in methods of reworking condemned powder. Hall has devised a successful plan by which to rebuild spent acids with oleum, for use in the manufacture of soluble cotton. G. F. Samuel has devised a very satisfactory magazine and thaw-house for dynamite, which is described, with scale drawings, in the *Engineering News* (page 692, June 25, '08). Accidents in thawing dynamite are due to the use of improper methods rather than to capriciousness in the explosive. Where no regulations prevail it is a common practice for contractors to put up a frame building covered with tar-paper, and having a steam coil in the bottom in which to thaw large quantities. Such buildings are exposed to fire from the outside, an overturned lamp inside, and overheating from the dynamite or the nitro-glycerol exuded from it coming in contact with the steam-coil. The style designed by the commission which investigated the explosion at the Park Avenue tunnel, New York, has never come into general use because, through defective circulation of air and lack of uniformity in heating, it failed

to thaw the dynamite. The author, in conjunction with officials of the Aetna Powder Co., built and tested an experimental thaw-house at Aetna, Indiana. The house is about 5 by 5 ft. inside, and is divided for convenience into two compartments for storing the material to be thawed, and a separate compartment for heating the air. The space to be used for the dynamite is so arranged as not to allow room for a man to enter, requiring the attendant to remain outside the building while handling the trays, thus avoiding danger of overturning a lamp in the building. The air is heated by passing over the steam coils, and a positive circulation is secured by a stack, which has an effective height of 15 ft. The quantity of air admitted to each compartment is regulated by dampers with circular holes in the bottom of the thaw-house, and the draft is regulated by a damper in the stack. The trays containing the dynamite to be thawed are staggered on their supports, presenting a series of baffles; these prevent the air from short-circuiting, and force it to come in contact with all the trays. The house is covered with galvanized iron to protect it against creeping fires in grass or underbrush. A $\frac{3}{16}$ -in. steel plate over the door, and gravel filling between the walls, form protection from stray bullets. Gravel is preferable to sand for filling, as the heat tends to shrink the wood on the inside, giving rise to cracks through which the sand escapes. Thermometers placed inside the house, but so arranged that they can be read from the outside, allow the attendant to keep the temperature under control. A temperature of 80°F. is considered desirable for thawing the dynamite. Good grades of gelatin dynamite may be thawed safely at higher temperatures, but with low grades of dynamite the nitro-glycerol is liable to separate if heated much above this temperature. The box containing the steam-coils is lined inside and outside with galvanized iron to protect it against fire. Where exhaust steam is used, about 70 sq. ft. of heating surface is required to raise the temperature from zero to 80°F. The capacity of the thaw-house is 540 lb. and it cost \$165.

As a contribution to the literature of accidents from the use or abuse of explosives, attention may be properly called to the sixth annual report on Fourth of July injuries which appeared in the *Journal of the American Medical Association*, September 5, 1908. The total number of killed was 163, and of injured 5460. The number of cases of tetanus from wounds was 76. The statistics are carefully analyzed, and measures to prevent this foolish waste are proposed.

Oregon consumes annually about 1,200,000 bbl. portland cement. Of this quantity about 270,000 bbl. is of domestic manufacture, two-thirds coming from California. Only one cement plant, that of the Washington Cement Co., at Concrete, exists in Oregon, which began operations in 1907. It has two 100-ft. rotary kilns, crude oil being used for firing. The limestone comes from quarries at Concrete, and the clay is derived from the banks of Baker river. The cement is rather high in silica, containing 24%, in this respect resembling the cement made at the Vulcanite works in Pennsylvania. It is below 2% in magnesia.

GEOLOGICAL AND PHYSICAL CONDITIONS OF TONOPAH MINES.

By WALTER P. JENNEY.

*A cluster of low volcanic peaks marks the site of the mining camp of Tonopah. It has in the past been an area of repeated eruptions of lava, beginning in the early Tertiary and continuing until comparatively recent geologic time. With the dying out of the eruptive phase of volcanic activity, there followed a period of intense dynamic action, accompanied by the formation of deposits of gold and silver ore. So recent has been the cessation of volcanic outbursts in this district that the rocks, like the eruptive formations of the Comstock, still retain a portion of their original heat. Notwithstanding the compara-

Montana-Tonopah Shaft.

tively late deposition of the ore, there are evidences in the mines that the formation of the deposits extended over a long period, with many disturbances and interruptions.

The order of eruption is the earlier andesite, the later andesite, and the rhyolite. The earlier andesite is white or light gray in color, soft, breaking with a rough fracture; the later andesite is darker, weathering near the surface with a deep brown or purple tint, so that it is usually readily distinguished from the earlier andesite; the rhyolite breaks with a fine-grained, splintery fracture, and is commonly light greenish-gray. The general dip of the andesites is to the north, at angles usually from 15 to 45°; the rhyolite sheet, being intrusive in the older lavas, often does not conform to this dip, and in some areas is nearly horizontal. The earlier andesite is the great

*Abstract from the *Tonopah Miner*.

ore-bearing formation of the district, and for this reason is called by the miners the 'lode-porphyry'; the rhyolite in places carries workable deposits of ore; while the later andesite, known as 'cap-rock', is usually barren. Owing to causes not necessary to discuss, the veins are larger and more regular where traversing the earlier andesite, and often contract in width, or pinch out altogether on entering the rhyolite. In some instances, however, the veins pass from the lode-porphyry into the rhyolite without material change in breadth or richness.

The favorable nature of the earlier andesite as a wall-rock is shown by the production; more than 90% of the ore extracted from the mines of Tonopah has been stoped from veins in that formation. In this the ore deposits conform to the general law of selective deposition, namely, that some geological formations appear to be everywhere barren of ore; others occasionally carry small deposits, workable where the conditions are exceptionally favorable; but in each mining region certain strata are ore-bearing in a degree exceeding all other formations combined.

The earlier andesite appears at the surface in a limited area, in ground owned by the Midway and by the Tonopah Mining Co., where it extends to a depth of 500 to 600 ft.; elsewhere it is capped by the dark-colored later andesite, or by flows of rhyolite. Beneath these capping formations the earlier andesite has a much greater areal extension and stretches east and west in a broad belt, extending from the Belmont mine, at the extreme east of the district, to the Tonopah Extension and Golden Anchor properties on the west, a distance of nearly a mile. In the Tonopah and Midway workings the belt is developed over a breadth of 1000 feet.

In prospecting the Tonopah mines the problem is largely the exploration of the lode-porphyry, or earlier andesite. Owing to the fact that all the ore deposits known in the district are subsequent in formation to the intrusion of the youngest rock in the series, the rhyolite, in following the veins in depth, certain places are found where conditions have been such that the ore departs from the earlier andesite and cuts through the underlying rhyolite. In the ascent of the solution toward the surface the veins usually terminate on reaching the cap-rock; from this cause many of the productive veins are 'blind' and do not appear at the surface. Only on the Tonopah and Midway properties, where the earlier andesite-flow covers the surface, do the veins outcrop with pay-ore. Other orebodies spring from the contact of the rhyolite with the earlier andesite (which forms the foot-wall or south boundary of the lode-porphyry belt), and extend upward in the andesite. In the West End and MacNamara mines, sheet deposits of high-grade ore occur on this contact. Some of the larger veins, when followed on the dip, go down in a series of flats and pitches (like a flight of giant steps), in which the horizontal travel of the vein to the north is greater than the vertical descent on the normal dip. This tends to carry the ore-bearing fissures toward the north side of the earlier andesite belt.

There is a peculiar early-formed fault-fissure, filled

with volcanic mud, which cuts through all the igneous flows and outcrops at the surface, from the Belmont mine west to beyond the Midway, known as the Mizpah dike, and while not ore-bearing, it has influenced the deposition of orebodies along its course. In the deeper levels of the mines there is evidence that the waters which formed the ore in some instances came up through channels alongside the dike.

The ore formation may be described as a broad belt of fissure veins, often closely spaced, traversing the district in a general east and west course. The extent of this mineral belt is undetermined; continuous stopes and connected levels reach from the Belmont mine, westerly through the Tonopah, Jim Butler, Montana, Midway, MacNamara, West End, and Tonopah Extension mines. With present development, ore deposits are opened along the course of the belt for nearly a mile, and are distributed over a breadth, north and south, of 3000 ft. The veins vary widely in width and often subdivide into branch veins, which not infrequently equal in size the original fissure. The great output of the camp is drawn from stopes averaging 4 to 5 ft. wide.

The ores are largely quartz, carrying silver glance (argentite), ruby silver (pyrargyrite), and the so-called 'brittle silver' (polybasite), together with chalcopyrite and other sulphides bearing gold and silver. The ratio of silver to gold in the ores is quite uniform throughout the district, being 90 to 100 oz. silver to 1 oz. gold; in the bullion produced, about one-third the value is gold. The grade of the ore as sent to the mills ranges in assay value from \$12 to \$50 per ton. The Tonopah ores resemble in mineral character and in the ratio of gold to silver those of the Comstock.

The Tonopah Merger Mining Co. owns the Salutation, Limerick, Limerick No. 2, Sky, Sky No. 2, and Sky No. 3, lode mining claims and fractions, and also the Golden Anchor property, embracing the Golden Anchor, Triplet, and Black Mascot patented claims. The Golden Anchor shaft is sunk to a depth of 855 ft., with levels at 400, 500, 740, and 840 ft. The shaft is equipped with machinery, air-compressor, and so forth, capable of exploring the ground to a depth of 1200 feet.

The shaft starts in the 'cap-rock', or later andesite, and continues in that formation to a depth of 550 ft., the 400 and 500-ft. levels being in later andesite. Below 550 ft. the shaft is in rhyolite to the bottom. An important development is made on the 840-ft. level, a cross-cut run north entering the lode-porphyry, or earlier andesite, at a point 290 ft. from the shaft. More important is the long cross-cut north from the Tonopah Extension shaft on the 1050-ft. which passes 530 ft. east of the Golden Anchor shaft, cutting through the intrusive rhyolite sheet, and penetrating the earlier andesite beneath the Black Mascot claim.

The workings of the Tonopah Extension mine lap the Golden Anchor territory on the south; the Tonopah Extension vein dips north, and the stopes on the 600-ft. level parallel the south boundary from which they are distant 250 ft. A 30-stamp mill, with a capacity of 135 tons per day, is now in process of construction on the Tonopah Extension.

RYE VALLEY GOLD MINES, OREGON.

Written for the MINING AND SCIENTIFIC PRESS
By AUGUSTE MATHEZ.

A few miles across the Idaho border, in Oregon, between Huntington and Baker City, is an interesting gold district, practically unknown except locally. The camp is controlled by the Commercial Mining Co., of Portland, Oregon. The postoffice address of the mine is Rye Valley. From both Huntington and Baker City are good wagon-roads to the mine. The interesting features of the property are the unusual widths of vein and high assay value of the ore, as far as developed. Near by is the old placer field of Mormon basin, some of the gold from which undoubtedly came from the lode-mines now being operated. It was these placer-fields that attracted the attention eight years ago of the representatives of some commercial travelers who had organized a prospecting company called the 'Commercial'. They bought some prospects, located others, and developed

Entrance to Tunnel Rainbow Claim.

what is known as the Rainbow mine. It is spoken of as follows on pages 289 and 290 of the United States Geological Survey, Volume 1908, Production of Gold, Silver, etc., in 1907:

"Mormon Basin district mines are mostly in Malheur county, but there is one important property which lies just over the border in Baker county. This is the Commercial Mining Co. (Rainbow) mine, which has a mill of 19 stamps, consisting of one battery of 5 stamps and 14 individual stamps. The mine is a large producer."

The gold in the Rainbow mine is in a basalt dike 300 ft. wide, between a limestone foot-wall and granite hanging wall. The whole dike assays \$2.40 gold per ton, and there are two 30-ft. widths in it that yield \$3.10 gold per ton. On the foot-wall side of the dike a quartz enrichment occurred, generally accompanied by a more porphyritic structure of the basalt, due to the slower cooling of the mass, and, therefore, a more perfect crystallization of its constituent minerals occurred. The interior rock of the dike is generally fine grained, and through the microscope shows characteristic basalt needles. The silica content is 52%. High assay values occur in chimneys or shoots along the foot-wall, averaging between 200 and 300 ft. long, one of these having a width of 10 ft. and a length of 240, with an average of \$36 gold per ton. Beautiful free-gold specimens occur in this shoot, containing specks of gold the

size of a pea. To a depth of 200 ft. below the surface the ore is free-milling; but at 300 ft. it has changed into an arsenical iron pyrite of considerably greater width, though assaying only \$10 per ton. It is an excellent concentrating ore. The 400-ft. level shows that the silicification extends to that depth. The company has just begun driving.

The history of the mine is interesting and odd. As stated before, about eight years ago some commercial travelers living in Portland decided to go into the prospecting business, and selected one of their number, W. E. King, the present manager of the mine, to go into the field. The result was his purchase of some prospects which he has developed into the present mine. Gold was found from the start, and hence the company's oddly constructed mill of seven 2-stamp batteries and one 5-stamp battery, the batteries being added as required. Up to date the mine has produced \$280,000 of gold bullion. No account has been kept of the amount of ore treated, but there are about 30,000 tons of tailing of an assay value of \$3.50 per ton. The mill is equipped with concentrating tables, but not over 6 to 10 tons of concentrate are made per month. The mill has a capacity of 40 tons daily.

Other companies are operating in the district, with apparent success, and there is reason to believe that this may become a prominent gold camp. Three thousand dollars in gold was recently taken out of a surface pocket on the Osceola claim, situated between the Humboldt mine and the Rainbow claim, belonging to the Commercial company. Some of the coarsest of the gold was broken from the rock, the largest pieces weighing over an ounce, and were melted in the Commercial company's assay office. In this clean-up 108 oz. were melted, assaying 652 fine.

CARBURETORS FOR GAS-ENGINES AT MINES.

Written for the MINING AND SCIENTIFIC PRESS
By E. N. PERCY.

Too often a gas-engine, primarily constructed for pumping, or marine work, or for farm use is sold for mining purposes, and connected to hoists, rock-crushers, air-compressors, or other machines, wholly without reference to its flexibility, weight of fly-wheel, or suitability for the duty. Then the miner and sales-agent both wonder why the engine is so cranky, why the belts break, why the governor will not work, and things in general are unsatisfactory. While the jackets are frequently found choked with lime deposits, the power low because of high altitudes, and the engine unsuited to work in hand by having too high or too low a speed, unsuitable fly-wheels, or the whole construction too light and cheap for the work, the most common trouble is with the carburetor. In the first place, mining calls for more carburetor-action than any other class of work; in the second place, the practical miner is more skillful at other things than with carburetors, and there is nothing that can be seen when a carburetor is cranky.

Rock-crushers, air-compressors, hoists, and other mining machinery are all of a class where the load varies suddenly, which is hard on a carburetor.

Most gas-engine manufacturers make their own

carburetors, with more or less success. Many a fine engine would give better satisfaction if equipped with a carburetor made by people who made nothing else. It is easy to make a gasoline engine run with almost any carburetor, or even by spraying a little gasoline into the pipe; but it takes the best of carburetors to control an engine under all speeds and conditions, with sudden slow-downs, and sudden opening of the throttle, in the case of a hoist. It is easy to get and adjust carburetors that will do this to the last word, but not by guessing. 'Hit and miss' is a satisfactory way of governing an engine for constant speed, but for careful governing under all conditions, and varying speed, as with a hoist, the throttle or gas-valve must be resorted to.

A hoisting engine that is to be shipped to a high, cold, altitude, that at times is very warm, should be throttle-governed, should have the best possible carburetor, and the compression should be increased $2\frac{1}{2}\%$ for each 1000 ft. of elevation. Under these conditions, it will give the same power as at sea-level. Every provision should be made to pre-heat the ingoing air to the carburetor; also, the carburetor might be jacketed with warm circulating water. Any high-grade carburetor can be purchased with or without a jacket. It should be so arranged that the warm air and jacket-water may be shut off in warm weather. Provision should be made for the inlet pipes to be kept warm, either by having them close to the engine, or by water-jacketing them. Assuming in cold weather, that the engine has just hoisted a load, and is left running idle for some time, the pipes being very cold, a part of the gasoline is being condensed all the time, because it goes through the pipes so slowly. A sudden call comes to hoist; perhaps a man's life depends on it; the throttle is thrown open, the air at increased velocity picks up all the loose gasoline on the sides of the pipe, the mixture is so rich that it will not burn, and the engine chokes or stops, and must be gradually brought up to speed. The gasoline-pipes from the carburetor to the cylinders should be comparatively small on a mine-hoist, so that the gasoline is always in suspension, even at slow speeds; but this speed should not exceed 20,000 ft. per minute at working load, or the rarification at high altitudes will be excessive and cut down the power; but in spite of this it is customary to send out stock engines for this work, with large pipes, and stock carburetors intended for one speed only. In these cases, it is better to keep the engine at one speed and to govern with the spark, but this is hard on the exhaust-valves, and soon burns them up. The right solution is to get a proper carburetor, that feeds the same mixture at all speeds.

A good carburetor should be jacketed, if necessary, for the work; should have main and auxiliary air-inlets, both capable of adjustment separately from the throttle, a needle-valve or changeable nozzle-tube, and an adjustment for varying the level of the gasoline in the carburetor. This latter is an important point, because, first, the level never is the same for different conditions, and second, if it is not possible to adjust this, the carburetor will refuse to work properly when the levers are so worn that the level changes. The carburetor is then said to be 'worn

out', when, as a matter of fact, there is nothing in a carburetor to wear out, if this slight wear can be taken up. But as the movement of the needle-valve is to be measured in thousandths of an inch, a slight wear will throw out the entire action of the carburetor, yet few makes, even of the best known carburetors, have this adjustment. Also, the needle should be heavy, should slide in heavy guides, and be a ground-fit; too often, it is merely a pointed piece of wire, and if a carburetor drips any gasoline, it is a sign that this valve leaks, and most carburetors do. A leaky carburetor cannot do proper work, particularly at low speed; and this is the reason why an engine running slowly will frequently die down and stop, as the mixture gradually enriches through the leakage.

These remarks are only intended to apply to the highest class of work, with every call for slow speed, quick opening of the throttle, and the like, as it is perfectly possible to run a gasoline engine with a squirt can, or mixing valve, or a teaspoon, and obtain a certain class of result.

DEBRIS CONTROL IN THE SACRAMENTO VALLEY.

By A. D. FOOTE.

*In the matter of barriers for holding back the mining débris and other wash from the mountains, it may be thought that the attempts made by the State of California in the Yuba tend to discourage more work in that direction. The work done, however, should be remembered rather as a lesson well learned, to be used to future advantage. The breaching of these barriers was caused by undermining, that is, the water, after passing over the barrier, dug a hole on the lower side of it, and worked back underneath until the barrier fell from want of support. A hint may be taken from the English engineers in India; for a wall may be carried down into the river-bed on the lower side of the barrier far enough to prevent this undermining. This would remedy the immediate and local danger to the barriers, but there is a general action going on which must be remedied also. It is so well known as to need no comment, that rivers if left to themselves are eternally flattening their grade. That is, they are moving whatever forms their bottoms along down stream in the usual course of nature, and the steeper the grade the greater the action. If, therefore, some extraordinary cause fills up a river and makes its bed steeper, this cutting action will become rapid, and if, in addition to this, at a certain point in the river, all material coming from above be stopped, and held, then the cutting action below this point will be much more rapid, because, as the material is moved along, there is no other from above to take its place.

If barriers are placed in the Feather and Yuba rivers near the hills only, the movement of the vast accumulation of débris below the barriers will simply be accelerated, and they will pass downward into the Sacramento and soon undermine the barriers. As this material should not be moved into the Sacra-

*Abstract from 'Redemption of the Great Valley of California'. *Proceedings Am. Soc. C. E.*

mento, and as it is desirable to have barriers in order to prevent more *débris* coming from the hills, they must be erected at intervals all the way from the Sacramento to the upper barriers; this will break the river grade into steps, with reaches between so nearly flat as to prevent the movement of the coarse *débris* forming their bottoms. This would lessen the velocity of the current and require higher levees to hold the floods. The excess of the floods must be turned into the basins and pass off through the escape channels.

In building these barriers, shown in Fig. 1, it is proposed to use the cement grouting method for a large portion of the structure. The upper barrier may be added to, as needed, for generations to come.

Fig. 1.

miner, who, when he puts in his 'undercurrents', as he calls them (for an entirely different purpose), points the way whereby the lower strata or heaviest silt, rolling along the bottom of a channel, may be diverted and carried away. The sketch, Fig. 2, shows the process better than it can be described. The secret of it is that the slot or exit orifice extends entirely across the bottom of the channel, and the velocity of the water through this orifice is not retarded by the sidewise discharge channel underneath. By a suitable device to vary the width of the exit orifice, any desired quantity of the heavier silt may be removed. The only mishap it is subject to in working is that it may get clogged by water-logged sticks and leaves rolling along the bottom with the silt. Opening the orifice wide for an instant will generally clear it. It is thought a trap of this kind may be placed in the heavier silt-bearing streams (they might be built into the flat portion of a barrier) where sufficient grade can be found, and convey the semi-liquid silt in small flumes where needed.

Finally, in working for the benefit of the tiller of the soil, the placer mine is reached. With the barriers in the streams to hold the coarser part of the miners' *débris*, the finer silt goes to the soil, and the farmer gets more gold out of it, through his crop, than the miner in his riffles. It can be demonstrated in hundreds of instances among the foothills, that enormous crops are produced on soil made entirely from the 'slickens' of the mines, and even the raw slime from the stamp-mills, collected in terraces in shallow gulches by little brush dams. It seems as if the raw rock, so finely ground, presented its potash and phosphorus to vegetation in a form that can be readily assimilated. It is not probable that placer mining will ever become as large an industry as it

was before it was stopped by law, but any placer mining will benefit the farmer. At the same time it will throw more or less coarse material into the stream-beds, and this must be retained by raising the barriers oftener than would otherwise be required. It would be but reasonable, therefore, that the placer miner be taxed sufficiently to pay for the increased work required at the barriers, even if his silt does enrich the valley lands.

Timber varies in strength with moisture-content. Tests show that the strength remains practically constant above 35% moisture. For example, the bending strength of loblolly pine ran down from 14,000 lb. per square inch when dry to 7800 lb. at 40%, beyond which no further weakening was shown by specimens in which the moisture was at the fibre-saturation point. The 'free-water' in timber does not affect its strength.

Fig. 2.

As soon as the side streams entering the valley are placed under control, it is believed that the heavier silt following along the bottom of these streams may be segregated and conveyed in small flumes to reclaim much waste land which is now useless, such as the beds of old sloughs, low places that have become alkaline, and small swamp areas which cannot easily be drained. In Italy and the south of France, large areas have been reclaimed by this method, or *colmatage*, as it is called, and much may be learned from their experience; but, in segregating this heavier silt, something may be learned from the intolerable placer

without endangering its stability, and, if the surface becomes worn appreciably, it will be neither difficult nor costly to spread a few feet of concrete over it, during the dry season, and this, if kept moist until it has set, will be as good as the original surface. The sand and gravel beds of the streams entering the Great Valley of the Sacramento are perfect material for forming cement conglomerate if cement grout is forced into it. The operation is quite simple and rapid. Pipe is driven into the river-bed, if possible by the water-jet method, to the depth required for the foundation, and a force-pump drives the grout into the interstices until they are full of cement which on hardening forms the solid concrete. The grout may be forced in within a radius of from 3 to 6 ft. from the pipe, depending on the porosity of the bed material. In this manner, broad and deep foundations may be constructed on which to build movable dams and regulators, on nearly every stream entering the valley, at a cost of less than half the usual estimates for such work. Near the centre of the valley, where clay or adobe occurs, this method cannot be used.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Modern Quicksilver Reduction.

The Editor:

Sir—In his interesting article on Huancavelica in your issue of October 23, Mr. Strauss stated in referring to losses in the reduction of quicksilver ore, that "in Idria 20% of the mercury produced was caught as metal in the condensers but the mercurial soot in the furnace is collected and treated separately." It may be noted in passing that the soot is formed in the condensers and not in the furnace. From the context, the inference may be drawn that most of the mercury in a quicksilver furnace is obtained from the soot, whereas, at least in American furnaces, 70% or more of the mercury runs out of the condensers as pure metal. Spirek, in the *Mining Magazine* of April, 1906, states that in 15 years at Monte Amiata, in Italy, the amount of mercury obtained from the soot was only 6.5% of the total production; and that the total loss of mercury was only 4 per cent.

H. W. TURNER.

San Francisco, November 2.

Ship Subsidies.

The Editor:

Sir—I am not in favor of a ship subsidy, in the general sense. It is claimed by Mr. Aldrich and his supporters that an average tariff of 47% is needed in order to prevent foreigners from underselling us in our own markets. What chance, then, do we stand in foreign markets, where our manufacturers receive no protection? The creation of a merchant marine is a dream, unless we lower our tariff wall, and put our cost of production upon the same plane as that of the rest of the world. Consumers in this country are paying three billion dollars more annually for the manufactured products which they consume than they would if there were no tariff. Of this three billion dollars imposed as a tax upon the American consumers the Government gets, in the shape of taxation, only three hundred millions, and the manufacturers get the rest.

The only practicable way of increasing our merchant marine is for the Government itself to build the ships which are required for naval transport, scouts, and an auxiliary navy, and to keep them employed in times of peace by leasing them to private companies. These we can use in opening up new routes of trade, such as those proposed to the Orient, South America, and Africa, utilizing the ships as training schools for the Naval Reserve. We have a preponderance of fighting ships as compared with our carrying ships, and the latter are as necessary to the Navy as the former. Construction of these ships as a part of our auxiliary navy could be justified, but payment of vast sums in the shape of subsidy to the identical private interests which are sustaining the present

policy of protective robbery cannot, in my opinion, be justified.

You will perceive from the above that no thanks are due to me for the consideration shown the resolution on encouragement of shipping which was passed favorably at the recent Mining Congress; if I had been there I should have opposed it.

FRANCIS G. NEWLANDS.

Reno, Nevada, October 24.

Slime Concentration.

The Editor:

Sir—Taking up the subject of slime concentration, with its accompanying queries so intelligently put forth by 'C' in a recent issue of your journal, I beg leave to submit the following data relating to a simple device for the recovery of fine 'float' mineral and mineral in suspension carried off by the clear water overflow from the settling boxes or mineral traps placed below the vanner floor.

A variety of devices is in use, each mill seeming to have its own, but the common practice is to place a series of shallow oblong boxes side by side, allowing the mineral-bearing waters to enter at one end, discharging into its neighbor at the opposite end, alternating through the series. This method looks effective, for, upon examining the boxes the bulk of the mineral is found in the first box, and in the last there is but little. If one will filter the discharge-water from the last box for an hour, he will be disillusionized, and perhaps elated, especially if it happens to assay more than 'two bits' per pound, and he will endeavor to devise some means of stopping it. Various filtering devices have been tried and proved successful, but they require much attention, and have to be destroyed when cleaned up, so that few mills bother with them. Hence this communication.

The principle that the following described device operates upon is gravity, aided by attraction. A reservoir is filled with clear water, large enough to present an absolutely tranquil surface, with a separate compartment for the mineral-laden water to discharge into, for the suspended mineral to settle in, and for the 'float' mineral to accumulate toward the side-walls of the compartment. Some of it will there agglomerate and ultimately settle; the balance will circulate as a slimy scum along the walls of this compartment, retained there because, in order to pass to the discharge it must settle vertically through quiet water some 2 ft. 6 in. deep. This apparatus should be constructed preferably of concrete, but one may substitute wood and obtain the same results.

Build a tank 8 ft. wide by 16 long by 3 deep out of 2 by 12-in. plank, resting on 6 by 8-in. sills 3 ft. apart, the side-walls retained by 6 by 6-in. posts mortised into sills and caps, or otherwise secured at the option of the builder. Designating the end of the tank nearest the mill the intake, proceed by measuring off five spaces along the side-walls 2 ft. apart, commencing at the discharge end of the tank. Next cut 20 pieces of 2 by 4 each 3 ft. long, and nail two of them to the side-walls vertically at each space previously measured, placing each piece 11

in. on either side of the space-line, and parallel with the same, forming guides for floating partitions which may be easily raised or lowered. Next place a piece $1\frac{1}{2}$ in. long in the bottom of the first set of guides nearest to the discharge end of the tank; in the next pair of guides place $2\frac{1}{2}$ -in. pieces on the bottom, and so on with each succeeding set, increasing the length 1 in. Then build partitions of 2 by 12-in. planking, fitting each length snugly but not tight, leaving it to be raised. This means cutting 10 pieces of 2 by 12, scant 8 ft. long, and five pieces of the same length, but decreasing an inch in width to correspond with rests in the guide-bottoms. Surface the edges and secure them together by spiking on three pieces of 2 by 6 of the same length as the width of the partition, one at each end, and one in the middle.

Means for emptying the tank and cleaning up are provided as follows: bore a hole $1\frac{1}{16}$ in. diam. in the bottom of the tank about 1 ft. from the wall at the discharge end, which, if the bottom is level, may be anywhere across the width, but if not level, put it at the low side as above. Next take a piece of 1-in. pipe about 7 in. long, thread one end for an ell, thread the other end back $3\frac{1}{2}$ in., dope the threads, put on the ell, and then screw the long-threaded end through the bottom of the tank from the outside, allowing $1\frac{1}{4}$ in. of threads to come through. Connect a short piece of 1-in. hose 4 ft. long, the loose end attached to a short block as a buoy, and when ready to empty, a funnel with some filter cloth stretched across the mouth may be inserted in the hose as a safeguard. Cut a piece of pipe long enough to extend from the ell to the outside line of the tank-bottom, put on a gate-valve, and connect it with the ell. Fill the tank with clear water, leaving out the partitions until the tank has swelled tight and all leaks are checked. This may take two or three days and is important. The tank being in readiness, turn in the amount of clear water nominally discharging from the mineral boxes, and let the tank overflow. This will indicate the inaccuracies of measurement. Then dress off an average of $\frac{5}{8}$ in. of the top of the discharge end of the tank, finishing with a draw-knife. The prime object is to have the water flow over the edge in a thin even sheet from side to side. Keep a small piece of window-glass ready. It will be found useful in removing any swelling of the wood retarding the evenness of the flow.

Set each partition in the proper guides, and, with the valve closed tight, no leaks developed, and the water overflowing uniformly, shut off the water and lead in the mineral-bearing water from the mill.

All the mineral will be found practically in the large head-compartment, 'float' and all. It cannot get out; it must go to the bottom. It will stand sudden excessive flows caused by washing down the concentrator floor. If the head-compartment fills to near the bottom edge of the first partition, carefully draw it out, thus increasing the capacity.

To clean up, which should not be done too often, select a time when the mill is shut down, and open the bottom valve, letting the water out slowly through the floating hose. This will empty it to

within 2 in. of the bottom, possibly a little less, but by boring a $\frac{1}{2}$ -in. hole through the discharge end from the outside on a level with the bottom, the tank may be drained dry, taking care to filter the last carefully. Let it dry a day if possible; then shovel it out, brush and sweep it as clean as possible, plug the bored hole, fill the tank with clear water to overflowing, and replace partitions.

In conclusion, for the benefit of those conservative gentlemen who want to make a test, take a spare mineral box, put in a partition 2 ft. from the end, extending to within 1 in. of the bottom, fill to overflowing at the opposite end from the partition, by having the partition-end raised $\frac{1}{8}$ in. above the level, and let just a little water flow steadily; take a handful of slime from a 'save-all' and throw it in the compartment, and notice where it goes.

Researches Upon Cripple Creek Telluride Ore.

The Editor:

Sir—As the MINING AND SCIENTIFIC PRESS was one of several American journals that published an article 'edited by Thomas B. Crowe', which appeared in the Chemical, Metallurgical & Mining Society's *Journal*, I beg to hand you herewith a copy of a communication that I am addressing to the society referred to, which might interest your readers.

"Chemical, Metallurgical & Mining Society,
of South Africa,
Johannesburg, South Africa.

Gentlemen—Several American mining journals having published an article 'edited by Thomas B. Crowe', which evidently appeared in your journal, we have thought it might interest your membership to know that the process which Mr. Crowe describes, is not one of his invention as you might infer, but the invention of John Collins Clancy. It is the subject of Transvaal Patent, No. 90, of 1909. Further, the same Thomas B. Crowe was Mr. Clancy's second assistant during a portion of the time that Mr. Clancy was the chief chemist of the Portland Gold Mining Co., at the time that Mr. Clancy successfully demonstrated the working of his process for the treatment of telluride ores on a large commercial scale without roasting. It was during this period of association that Mr. Clancy gave Mr. Crowe access to all of his books and data.

"It would hardly seem necessary to add anything further than to say that the Portland company is working under a written executed license-agreement from Mr. Clancy to use his process, and that the successful operation of the new 300-ton plant which that company is now building on its own mine at Victor, Colorado, is based upon the success of the exhaustive demonstrations made with the Clancy non-roasting process."

HENRY B. HAIGH.

Grahamite is found in Oklahoma filling fissures in the form of veins or dikes that cut across and extend with the bedding. In the Ouachita mountains it occurs in both Ordovician and Carboniferous rocks.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Selenium is one of the rare elements whose properties have given it considerable interest. In the dark it is a poor conductor of electricity, but in the light it becomes a good conductor, and on account of this peculiarity it is used in a number of electrical devices. It has been used in telephoning along a ray of light, and also in transmitting pictures by telegraph.

Denatured alcohol costs more than gasoline and the quantity of denatured alcohol consumed by an alcohol engine as ordinarily constructed and operated is in general relatively greater than the quantity of gasoline consumed by a gasoline engine of the same type. It seems reasonable to expect a greater general improvement in alcohol engines than in gasoline engines.

Esmeraldite was described first by A. S. Eakle. It is a hydrous ferric oxide from Esmeralda county, Nevada. It occurs in small pod-shaped masses enclosed in a yellowish brown earthy and highly silicious limonite. The fracture is conchoidal and the mineral very brittle. Hardness 2.5, gravity 2.578, lustre vitreous, color coal-black, streak yellowish brown. The mineral resembles melanosiderite.

Strength of current employed in American copper refineries is 12 to 15 amperes per square foot of cathode surface. The voltage is increased with the number of tanks in series. As there is danger of loss from leakage under high voltage it is not safe to supply a large number of tanks from a single-feed wire. The theoretical pressure of 1.16 volts required to precipitate copper from the sulphate solution is reduced in practice to $\frac{1}{6}$ to $\frac{1}{3}$ volt, by virtue of the soluble anode.

Monazite is one of the minerals which, for a long time, was considered rather rare in its occurrence, but, upon a commercial demand arising for it, prospectors and engineers soon found large deposits of it in the Carolinas and Brazil, and the supply has always been able to meet the demand. During 1908 further sources of supply of monazite have been discovered and developed in Idaho. North and South Carolina, however, are the only States that have thus far put any monazite on the market.

Molasses is occasionally used as a boiler compound, but alone is dangerous if used in any quantity. Under boiler temperature and pressure it undergoes a complex decomposition. It gives rise to the formation of corrosive organic acids and causes a separation of carbon which is liable to deposit itself in the tubes. The theory on which the use of saccharine substances is based is that it causes the formation of soluble sucrares with the calcium salts present. However, at boiler temperatures and pressures the tricalcic sucrares and possibly the sesquicalcic sucrares would be formed. The precipitate, however, is light and remains in suspension if the circulation is good.

Concentration is an important factor in effecting a change of chemical activity. Thus the speed of interaction of a body, when other conditions are constant, is directly proportional to its concentration, that is, the closeness of the particles of the substance in the region of action. In the case of a gas, for example, when oxygen at 700° is compressed in contact with barium oxide, it unites with it to form barium dioxide; but when the pressure is reduced to an incomplete vacuum, oxygen is liberated, and the dioxide is reduced to monoxide.

Cobalt occurs at many places in the United States, but all of the 1908 output came from Fredericktown, Missouri, where it is produced in connection with nickel and copper from concentrate obtained in mining for lead. The principal uses of cobalt are in making glass and pottery. Cobalt oxide imparts a beautiful blue color to glass. Some salts of cobalt change in color on absorbing water, being blue when dry, but pink when damp. A familiar hygrometer making use of this property is a doll whose dress is blue in dry weather and pink in damp weather.

Combustion of nitrogen in oxygen is an equilibrium for each temperature between the nitric oxide produced and the nitrogen and oxygen, hence the amount of nitric oxide produced at any temperature cannot exceed that corresponding to the state of equilibrium for the particular temperature. The following figures give the percentage produced: at 2200°C. the gases contain 1% nitric oxide, at 2571°C. 2%, at 2854°C. 3%, and at 3327°C. 5%. Therefore the air must be heated to as high a temperature, and the products cooled as rapidly, as possible to reduce the decomposition of the nitric oxide to free nitrogen and oxygen to a minimum.

Knots in timber are not necessarily a cause of weakness. When situated near the neutral plane they may act as pins, and tend to strengthen a beam against failure in longitudinal shear. Knots in the top of a stick are not so weakening as those in the bottom. A comparatively small knot situated near enough to the lower edge of a beam to turn the grain off is more harmful than a larger knot so placed as to allow the grain to be continuous in passing. Tests recently made under Government auspices confirm the fact that the position of a knot is a much more important factor than its size, and knots on the tension face of a beam should be avoided.

Tellurium, which is classed as a metalloid, is supplied as a chemical curiosity in the form of a black powder and as a metallic-looking substance with a fine columnar crystal form, in color somewhat resembling tin. No use has yet been discovered for tellurium, and many tons of this element are annually wasted in Western mining districts. Some of the compounds of tellurium have an offensive, all-pervading, and ineradicable odor. Chemists who have been experimenting with tellurium say that after three months exposure to sun, wind, and rain the clothing worn by them while they were making these experiments, although it had not come into contact with the tellurium compound, was still so unpleasantly scented that it had to be destroyed.

Special Correspondence.

NOME, ALASKA.

Water Shortage. — Output. — Ditch Systems — Kougarak District. — Pioneer Mine. — Iditarod. — Discovery on Sweepstake. — Winter Plans. — Quartz Mining.

The mining season for 1909 has just closed and the output is nearly one million dollars less than for last year. This shortage is due in part to the fact that the rich Third Beach pay-streak which has contributed so largely to the output during the last four years is now practically exhausted, and in part to the fact that this has been the driest season in the history of mining on Seward Peninsula. The snowfall of last winter was exceptionally light and it melted before mining operations were fairly under way. Only a few light showers of rain fell until about the middle of September. Following the first heavy rains the mountains and higher hills became covered with snow and the temperature was soon lowered to the freezing point in the valleys. The miners derived but little real benefit from the precipitation. By September 25, owing to the cold

ditch enterprises, notably the Taylor Creek ditch in the Kougarak district, the Fairhaven ditch in the Inmachuk River district, the Candle Hydraulic Co.'s ditch in the Candle Creek district, and several others of lesser note in different parts of the Peninsula brought large tracts of rich gold-bearing ground within the producing area, had it not been for the unwelcome fact that the lack of ample annual rainfall causes the sources of water-supply for these long and expensive canals to run almost dry, so that streams which ordinarily are scarcely fordable on horseback could be walked across during the past summer in one's Sunday shoes without getting wet.

The great Miocene ditch system, embracing fifty odd miles of main line and laterals, which delivers water from the heads of Nome and Snake rivers to the vicinity of Anvil creek, and which has a capacity of about 3000 miner's inches, was reduced to less than 300 in. during the latter part of this season. The Seward ditch, about 40 miles in length, taking its water from Nome river and delivering it around the foot of Anvil mountain, was likewise reduced to about one-fifth of its carrying capacity. The Topkok ditch, taking its water from Kootcheblok and Big Skookum to the immensely rich diggings on Daniels creek, was practically dry after the snow-water ran off in June and until the late

September rain. The Ophir creek and Parantulik river ditch system, belonging to the Wild Goose Mining & Trading Co. and supplying water to Ophir creek, maintained the steadiest supply and highest efficiency of all the ditches in the Peninsula. Its supply was probably never less than 60% of its carrying capacity, which is approximately 3000 miner's inches, and consequently the Ophir creek output for this season was normal, a fact which cannot be claimed for any other district depending upon ditch water.

Although no data are obtainable dating back further than the discovery of gold on Anvil creek in the summer of 1898, basing opinion upon the climatic conditions which prevailed during the first nine years of the history of mining on Seward Peninsula, it is confidently believed that the drought of the past two seasons is exceptional. In spite of the discouraging conditions from which they are emerging at the end of this season, the future still holds a rainbow of promise for the majority of those who have

Nome Beach.

northerly breezes sweeping down over the snow-capped hills, practically all sluicing operations are discontinued, except on the various dredges scattered about the Peninsula, most of which continued to run until the third week in October. The total gold shipped since the opening of navigation, as shown by the records of the customs office, to which reports are made by all the banks and by the post office, is \$3,975,196.58, and as compared with the previous five years the figures are as follows: 1904, \$3,818,002.82; 1905, \$4,648,855.92; 1906, \$7,290,724.83; 1907, \$6,612,489.72; 1908, \$4,937,253.51; 1909, \$3,975,196.58. It is estimated by the banks of Nome that at least 10% of the gold produced on Seward Peninsula is either shipped or taken to the outside direct by the producers and is not reported at the local customs office, though all gold sent by mail or by the banks is so reported. It will be observed that the output has steadily declined since 1906, which was the banner year for the famous Third Beach pay-streak. This showing, however, must not be taken to mean that Seward Peninsula has passed the zenith of its producing power and is on a permanent decline. On the contrary, it is firmly believed that the development of its vast gold-bearing areas is in its infancy and that soon its banner year will be annually eclipsed. As has been stated, this season was the driest in ten years that has elapsed since the discovery of gold on Anvil creek. Had it not been for this extraordinary drought the records would show far different results, even though the rich pay-streak of the Third Beach has been steadily on the wane. The completion since 1906 of several large

invested their money in ditch enterprises. The immediate effect, however, will probably be the complete cessation of further ditch building on the Peninsula until those already constructed have proved successful. In the meantime some effort is being made looking toward storage reservoirs, and particularly toward impounding snow over large areas in the basins and slopes at the heads of the ditch systems.

The Taylor Creek Ditch Co. in the Kougarak district has expended a great many thousands of dollars during the past season in constructing snow fences, which it is hoped will impound sufficient snow to be of material aid in maintaining a water-supply during a dry season. This company, which is managed by Andrew J. Stone, who is also one of its leading stockholders, owns many valuable claims along the Kougarak river and some of its tributaries and has expended during the last four seasons more than three-quarters of a million dollars in the purchase of claims and the construction of an extensive ditch system. Though but little actual mining has been done by the company so far, a large area has been prospected with very encouraging results, and Mr. Stone has now determined to provide against a future shortage of water which has so hindered his operations during the last two years, by the installation of an immense power plant on the lower Kougarak river about 12 miles below Igloo, where he proposes to generate electric power which will be transmitted to the vicinity of his mines, and with motor-driven pumps will supply water from the main river to his ditch system, through which it will be distributed to the various claims. Although the power

plant will be situated near the river the power will be derived from several streams which drain the north slope of the Sawtooth mountains. The waters of these several streams are to be conveyed through wooden flumes aggregating 11 miles in length to an immense glacial basin which forms a sort of amphitheatre at the head of one of the streams, and which by the building of a dam across the lower end will form a reservoir covering several hundred acres. The aggregate volume of water available at this point during the lowest water of the past season was 6000 miner's inches, according to measurements made by Daniel A. Jones, to whom I am indebted for this information. From the reservoir a pipe-line will be laid three miles down the slope to a point near the Kougarok river, giving a total fall of 1020 ft. Pelton wheels will be used and it is expected to generate at least 12,000 hp. The company will not only develop power for its own operations and its neighbors in the Kougarok, but will deliver power to the Nome, Solomon, and Council districts for use on dredges and other mining operations. It is estimated that the plant when completed will cost \$750,000. Mr. Stone's faith in the future of the Kougarok district as a great gold producer grows stronger each year despite the obstacles to be overcome, and he deserves great credit for the persistent effort he has put forth to develop this promising field.

Advantage has been taken of the extremely low water during the past summer to prospect the bed of the river in the upper stretches of the Kougarok, with the result that some rich gravel has been discovered. Dolan and McFadden, who were among the first to attempt mining this season on the main river, are reported to have mined \$160,000 by the pick and shovel method during the season, and many go so far as to say that a stretch of eight miles along the upper river is equal in richness to Nome's famous Anvil creek. The first stampede to the Kougarok River district was in 1899 by prospectors from Nome and Council City districts, and the first real effort at mining was made in the season of 1901. This proved more or less of a failure, due in part to irregularities of the pay-streak on the creeks on which the attempt to mine was then made, and in part to the fact that the creeks upon which the pay had been discovered furnished little or no water during the larger part of the summer season. Then came an era of ditch building, and several big ditches were constructed from the head-waters of the river and its larger tributaries to various localities where pay dirt had been found. Following this ditch construction the discouraging fact was realized that the water-supply was limited except in season of heavy precipitation. Taken all together the history of Kougarok district has been one of much promise with very little performance. Nevertheless, it is beyond cavil that there is a vast amount of gold-bearing gravel in the basin of the Kougarok, and the larger stream-beds will probably furnish dredging ground for many successful ventures. The smaller stream-beds and benches will give ample opportunity for power consumption from Mr. Stone's big power plant or any other.

Mining operations in the vicinity of Nome, although more active than elsewhere on the Peninsula, have been quieter during the past season than for the last three or four. The Pioneer Mining Co., working the rich area lying between Little and Anvil creeks, have, as usual, worked a large force of men and produced from their winter dumps and from their open-cut operations near Discovery on Anvil creek during the summer, about 20% of the total gold production for Seward Peninsula this season. Although reworking No. 1 Above Discovery on Anvil with wheel scrapers delivering to an elevated sluice-line, their chief operations were conducted on an old channel of Anvil creek lying off No. 1 and 2 Below Discovery. This channel is about 20 ft. deep from the present surface, 60 to 80 ft. wide within the bedrock rims, is covered by from 8 to 12 ft. of tundra muck, and is permanently frozen. Their method of working is to ground-sluice the surface muck from an area equal to the width of the channel by about 300 ft. in length. A pit is then thawed and excavated to a depth of 6 ft. below the bedrock surface in the centre of this block, and a self-dumping hoist is set up with the bucket dropping into this

pit. A line of sluices is built on the rim at sufficient elevation to provide tailing room for the entire block. At the beginning, operations are facilitated by thawing the gravel banks around the open pit with steam-points. The exposed gravel thaws rapidly, however, in the warm summer air, and the operations are quickly extended to all parts of the ground-sluiced area by radiating steel-rail tracks upon which half-yard cars are handled by two men. The gravel is shoveled into the cars, pushed to the pit, and dumped into the bucket of the self-dumper. It is then hoisted and dumped into a mud box at the head of the sluices and is washed with about 200 miner's inches of water. The surface of the ground-sluiced area is reduced in slices of about 3 ft. in depth. When the limits of the area have been reached, the tracks are lowered and a new slice is begun. The pay extends into the shattered surface of the schist bedrock from 2 to 4 ft., and this is usually the richest slice. A force of 20 men, including the foreman and hoist man, is used on each shift, and two shifts of 10 hours each are worked. The average number of cars handled on each shift is 400, representing approximately 400 cu. yd. per day of 24 hours. The average daily gross output of each plant is about \$2000. This company, under the able management of Jafet Lindeberg, its president and one of the first discoverers of gold on the Peninsula, has maintained the enviable position of leading dividend payer since the mining began here.

E. L. Blanck, Charles Vogel, and Howard Ames, operating the McKay Bench adjoining the Pioneer Mining Co.'s ground, under lease from McKay and Nussler, the owners, were fortunate enough to uncover the same rich channel that has been so profitable for the Pioneer Mining Co. After sinking several shafts and proving the continuity of the pay-streak through their claim, they accepted an offer of \$75,000 for their lease and turned it over to the Pioneer Mining Co. in the early part of September. The Bessie Bench claim owned by Boncher, Greenberg & Foster, which was flooded early in the summer by accidentally breaking through from the frozen ground in which drifting operations were being conducted, into the adjacent thawed ground, has again resumed operations. A rather novel plan was adopted to stop the heavy inrush of water through the gap which had been opened to the thawed ground. A series of holes was drilled from the surface intersecting the drift which had let in the water. A refrigerator plant was secured from one of the cold-storage companies of Nome, and through return pipes lowered into the drill-holes a circulation of ammonia gas was kept up for several days. This froze a solid block of ice, filling the drift, and completely cutting off the water. The mine was then pumped out and operations were resumed under the same conditions as before the accident.

Much interest is being taken by Nome people in the new strike on the Iditarod, a tributary of the Innoko river. Reports have been reaching here for more than a month past to the effect that a strike of extraordinary extent and richness has been made. Many of the miners and prospectors of this district have already joined in the rush to the new diggings and others are preparing to go as soon as the snow falls and sleighing is possible. Some of the business men have also caught the fever of the stampede, and stocks of merchandise are scattered all along the trail between here and the new diggings. Schied & Co., machinists and hardware dealers of Nome, are sending 200 tons of groceries and prospectors' supplies up the Innoko to Dishkakiet, to which point they expect the miners to come to buy their supplies. John Tesack and David R. Jekel, who have long been connected with the Pacific Cold Storage Co. of Nome, are also taking a \$10,000 stock of groceries and other merchandise to the new diggings. They expect to land it on the Iditarod in the centre of the new excitement. Ramps Peterson, another Nomeite, is somewhere on the lower Innoko at this time with a stock of the inevitable wet goods. The scene of the new strike is approximately 375 miles from Holy Cross mission of the Yukon river, and is reached by traversing the Shageluk slough 125 miles to the mouth of the Innoko river, thence 25 miles up the Innoko to the mouth of the Iditarod, thence 225 miles up the

Iditarod to Otter creek, which is the centre of the present excitement. Otter creek is approximately 75 miles across country from Dishkakot on the Innoko. The Shageluk slough and the Innoko river to the mouth of the Iditarod are navigable for river steamers, but no reliable information as to the navigability of the Iditarod is available. Reports reaching here from there are conflicting as to the richness of the strike, but all agree that the gold-bearing gravel is extensive in area. Some have said that pans of \$1.25 to \$2.65 have been taken from some of the prospect holes, and others that 5 to 10c. per pan had been found uniformly in a body of gravel 400 to 600 ft. in width and several miles long. It is claimed that numerous prospect holes have been sunk and all show workable ground. The gravel beds are from 5 to 10 ft. deep. As another evidence of the faith some of our people have in the new diggings, the Innoko Telephone & Telegraph Co. has been organized by O. A. Margraf, John Reik, J. M. Sloane, Ed. Young, and others, and a line is now being constructed from Kaltag on

Nome in Winter.

the Yukon river across country to Dishkakot on the Innoko, thence to Ophir creek and Otter creek. Two hundred miles of wire, two boxes of telephones, and all necessary insulators and other equipment were shipped from here to Unalakleet on Norton sound two weeks ago. As soon as the trails are in condition this material will be transported over the portage 90 miles to Kaltag, and it is claimed the line will be in working order from Kaltag to Dishkakot by January 1 next. This line will put the new diggings into touch with the outside world over the Signal Service line along the Yukon.

Another discovery of some promise has lately been made on Sweepstake creek, a tributary of the Koyuk river, which empties into the head of Norton bay. A party headed by Robert Brown, one of the pioneers of the Kougark, spent a part of the past summer in that district and returned here about October 1 with the report that they had discovered good prospects on Sweepstake creek. Brown has bought a big winter outfit and will return to the new find immediately. Another party headed by Sam Smith, an old timer here, is also taking a winter's outfit to the same locality. These diggings lie in the belt of country between the Council City and Candle Creek districts, and interesting developments are expected. Gerald O'Shea, the well known mine manager, who for the last two seasons has had charge of the Topkok Ditch Co.'s operations on Daniels creek, returned a few days ago from a trip to the Innachuk River district, over on the Arctic slope, with the news that the Box brothers have struck good pay driving in an old river channel under the great lava-bed which stretches for miles along the divide separating the Innachuck and Kugruk rivers. They have driven an adit from an outcropping rim a distance of 300 ft., attaining a depth of 150 ft. under the lava-cap. This follows the bed of the old channel, and they are now cross-cutting at the end of the adit and finding pay dirt. This old buried river was more than

a quarter of a mile wide and now lies under hundreds of feet of lava.

Dredging on the Seward Peninsula has been active this season, and with good results. Winter operations apparently will not be as active as formerly. Considerable prospecting is being undertaken, as usual, and some one may be lucky enough to uncover another bonanza pay-streak, but at present the known rich ground is quite limited in extent. This outlook has caused many of our prospectors and miners to stampede for the new strike on the Iditarod river, and many more, looking to a dull season, have gone to the outside for the winter. There will be about 1000 fewer people on the Peninsula this winter than last. The Nome district will furnish employment for about 200 miners, Candle and Kougark probably 100, and all other districts probably 100 more. A limited amount of work is being done on quartz mines. The Alaska Chief silver-lead mine on Lost river is working a small crew, and it is reported are meeting with encouraging prospects. The

Silseo antimony mine on Manila creek, a tributary of Nome river, is also working a small crew, and the Wheeler copper mine near Iron creek is working a few men. This property has a promising showing of copper carbonate outcropping at the surface, and the owners have shipped ten tons of this ore on one of the last boats to obtain a smelter test. Some work is also being done on the Ward copper prospect near the head of the Kougark river. It is said a 50-ton shipment of ore from this claim will be sent down over the snow-trail this winter to the terminus of the Seward Peninsula railroad on the Kougark to be shipped outside next spring. The Hurrah quartz mine, in which the Lane family has invested so much money, is still idle, although it was reported some time ago that Charles A. Ferrin, president of the Northern Mining & Trading Co., had secured an option on the mine and mill, and would operate it this winter. Some work is being done on the Lost river tin mine, owned by Crimm, Randt, and O'Brien, but the tin mines near Tin City, about which there was much stir a couple of years ago, seem to be numbered with the things that were. The McAllister gold prospect at the head of Nome river has lately had new

life infused into it by the striking of a pocket of ore showing much free gold.

WASHINGTON.

Supreme Court on Mining Titles in the Philippines. — Salton Sea Damages.—Water Power Census.

The United States Supreme Court recently decided the ownership of a gold mine in the Philippine Islands, and thus closed long drawn out litigation. The case was entitled *Reavis against Fianza*, the latter being a Filipino and the winner of the suit. The Supreme Court in effect held that the occupancy of land by a native of the Philippine Islands for a number of years forms a superior basis for a claim to the land than does settlement by an American. The property in controversy was a gold mine in Benguet Province, which had been operated for 50 years by the Fianza family, who are Igorrotes, without making any formal filing upon it. Reavis undertook to obtain a patent on the mine in 1901. The Philippine courts decided in favor of Fianza, and the decision of the Supreme Court sustains that finding. The opinion was by Justice Oliver Wendell Holmes, who said: "It sufficiently appears that the Fianza family had held the place in Igorrote fashion, and to deny them possession in favor of Western intruders probably would be to say that the natives had no rights on the statute that an American was bound to respect. It is suggested that the possession of Fianza was not under a claim of title, since he could have no title under Spanish law. But whatever may be the construction of Revised Statutes, Sec. 23, 32, the corresponding section of the Philippine Act cannot be taken to adopt from the local law any other requirement as to the possession than the length of time for which it must have obtained. Otherwise, in view of the Spanish and American laws before 1902, no rights could be recognized and the

section would be empty words." The decision of the California courts in the case of the New Liverpool Salt Co. against the California Development Co., in which the salt company was awarded damages to the extent of \$456,746 for alleged damages to its mines, may be reviewed by the Supreme Court. A writ asking for a re-hearing has been filed by the development company. The suit involved a controversy over the question of the responsibility for the overflow of the Colorado river into the Salton sink in 1905, by which the salt mines of the New Liverpool company were badly damaged. It was said by the salt company that the overflow was due to carelessness of the development company in the construction of the head-gates of its irrigation ditches, and the United States Circuit Court for the southern district of California held such to be the case.

A report just issued by the United States Geological Survey contains some interesting information regarding the water-power available in the United States. M. O'Leighton, the chief hydrographer of the Survey, makes the statement that flood damage in this country has increased progressively from \$45,000,000 in 1900 to \$237,000,000 in 1908. Mr. Leighton also discusses the developed and undeveloped water-powers of the country. Out of about 37,000,000 hp. available at the minimum flow of streams, but little more than 5,000,000 has been developed, or about one-seventh of the minimum available. A complete census of water-powers has been taken, but the undeveloped powers are determinable only by estimate. The State of New York has the largest development, with 885,862 hp., California standing next, with 466,774. The section of the country furnishing the greatest possibilities of water-power development is the northern Pacific region, including the basins of Columbia and the Sacramento rivers. Frederick H. Newell, director of the Reclamation Service, states that the irrigated land of the United States has increased from 3,631,381 acres in 1889 to about 11,000,000 acres in 1907, and fixes the limit of irrigable area in the arid region at about 45,000,000 acres, or more than four times the area now irrigated.

JOHANNESBURG, TRANSVAAL.

Diamond Market. — Government Mining Leases. — Grootvlei Shaft-Sinking. — Record Driving. — Gold Output for 1909. — Oil in Orange River Colony.

A discussion in which five or six months elapses between statement and reply is apt to become tame unless the theme is peculiarly interesting. The unscientific debate which has been taking place between the diamond companies of South Africa during the past year has only been saved from the stigma of pettiness by the inherent importance of the subject to all concerned in the welfare of the country. The controversy has its sources in three colonies, wherein operate three great concerns constituting the dominating factors in the world's diamond market. At the end of last year the chairman of De Beers (Cape Colony) told us forcibly of the market's critical situation and of his company's cautious policy of retrenchment, adopted—with painful results—to aid its recovery. Also of the indiscreet and suicidal policy of large-scale production in the face of the small demand, persistently pursued by the (Transvaal) Premier company. Then, a month or so later, the Board of the Premier responds with a forcible form of *tu quoque*, which may be summarized as an accusation against De Beers of responsibility for the overproduction which caused the crisis. Now, the chairman of the New Jagersfontein, Mr. Harris, denies that either De Beers or its Orange River Colony ally ever overcrowded the market, and was able to claim, as a result of the prudent policy followed by the older corporations, that "the diamond market has quite recovered" and that "the demand is now almost as strong as it was during the three years ending June 30, 1907." The renewal of steady business is dated from January 1, 1909, while the improvement in sales was conspicuous from July.

The announcement by the Transvaal Government that it was prepared to receive applications for a lease of the exclusive right to mine under certain portions of the farm Turffontein is notable for two reasons. The ground comprises certain 'bewaarpiaatsen' (depositing sites), machine-

stands, and water-rights, the mining rights of which were reserved for disposal by the Government, when the surface-rights were granted. The holders of these rights apparently get no prior consideration in the matter, and it is doubtful whether they will share in the benefits of disposal. The important points in connection with this Turffontein area are that it lies in the richest portion of the Rand, immediately below the Robinson, and that, though small in area, namely, 15.8 claims, it is being offered for public tender instead of being sold at some price agreed upon by negotiation to the adjoining companies, which can work it for the greatest profit. In publishing the terms of the Government's call for tenders, the *South African Mining Journal* refers to the scheme as an "impossible proposition." This is taking too unfavorable a view. Owing to the high value and great reef-widths of the ground, this small block of 15.8 claims could undoubtedly be developed with a new shaft, and, newly equipped, will be worked at a big profit. It would, however, be a most uneconomical undertaking with adjacent mines so well able to deal with the ore through existing shafts and with present mills. To the Robinson Gold Mining Co., the upper claims of the block could be sold for the utmost gain, and to the Crown Mines the lower. Companies which could mine the ore without equipping the ground or sinking a shaft would not be likely to compete wildly with each other for the acquisition of the ground, all the properties in this rich portion of the Rand being under control of Eckstein or the closely allied Consolidated Gold Fields. Perhaps the application for tenders is only formal. It is nevertheless unreasonable, since the Government should give greater consideration to the holders of surface rights or to adjacent companies. The *quid quo pro* will be balanced when the Government has very small blocks of deep-level ground for disposal, which could not possibly be touched by anyone save the companies within or adjoining whose areas these 'fragments' lie. In accordance with the accepted scheme, the Government stipulates that applicants for the Turffontein lease must guarantee a percentage of the working capital, and until flotation must provide evidence of his ability to furnish the necessary funds for the development and equipment of the mine, must float a company within two months of closing the agreement, must create no vendors', promoters', or founders' shares, and must offer 25% of the capital required for subscription to persons resident in the Transvaal.

The Grootvlei Proprietary Mines, Ltd., a subsidiary of the East Rand Mining Estates, has commenced two shafts on the farm Grootvlei, to the north of Nigel in the Far East basin. It may be fairly said that when these shafts cut the reef, and development is commenced, there will be no company on the Rand providing information bearing more vitally upon the industry's future prospects. So far the reef's position in this area has been learned by diamond-drill cores, which, for valuation purposes, are useless in the East Rand, with its erratically distributed gold. Messrs. Lewis and Marks have been a long time in entering upon the critical stage of shaft sinking, but the industry owes them a big debt for their pioneering work with the diamond-drill in the East Rand.

Another record in rapid driving has been established. This has likewise been accomplished in the Far East Rand. During October, two men made a footage of 334 ft. in 62 shifts in a 6 by 7-ft. drift. An average of 12.5 holes per round were put in, and the advance was 5.56 ft. per shift. This was done at the Modder 'B' gold mines. In the adjoining New Modderfontein, 349 ft. were advanced in one month in two drifts worked single shift, while the new Modder 'B' record has been made in a single face, worked double shift. Reckoned solely by progress per shift, the New Modderfontein's record remains unbroken, while the later performance stands first in merit regarding the actual progress of a single face during a month. The most significant conclusion to be drawn from these achievements, in conjunction with those announced by the Van Dyk company, is that the rock of the Far East Rand possesses exceptionally good breaking qualities, and that when any urgent connections have to be made underground at maxi-

mum speed, it is possible to calculate upon monthly footages far in advance of the rates to be safely assumed in Central Rand operations.

Seeing that there was a further loss of 4221 unskilled laborers (including 2157 Chinamen) during September, bringing the total loss for five months to 22,933, the output for the short month was not discreditable. The Transvaal's yield of £2,575,760 was, however, the lowest recorded since February. At the present rate it appears that the total yield for 1909 will be little more than £31,000,000, or one million more than 1908. This aggregate would be considerably below the estimate generally formed six months ago, when the severity of the impending labor shortage was not fully realized, and when 'expansion' was the cry of every mining interest.

The chances of establishing an oil industry in the Orange River Colony have been brought into prominence on several occasions since the war. Up to the present time there has been no market speculation over oil prospecting, although nearly every other mineral product has been given its turn of financial notoriety. It is to be hoped that the Free State Oil Exploration Co., Ltd., now in course of formation, will raise the desired capital to enable it to undertake its drilling program in the Ladybrand district, which has long been regarded as the most promising region. The venture is to be provided with £12,500 working capital, and this amount, judiciously expended, would throw a great deal of light on a question of interest and importance. The report by J. H. Ronaldson, attached to the prospectus, leads one to hope that the proposition will be tackled cautiously. It is a statement of facts from which no wildly sanguine conclusions are deduced. The more or less flat sandstone beds of the Stormberg series (Karoo system) are cut by diabase dikes, in which occluded oil has been found. This is considered to have probably been derived from some source, already containing oil, through which the dike passed. How deep this source may be and how rich in oil remains to be tested. Boring has already been commenced in the district, and a little oil reported at 900 and 1600 ft. Some gas was given off by this bore-hole and also at Harlismith, 140 miles to the northeast.

NEW YORK.

Copper Production for November.—New Copper Combination.—Ely Central.—Stock Market Conditions.

The official report of the Copper Producers' Association for November 1, showing production and consumption of copper in the United States for October, and the stocks on hand at the end of that month, compares with the two previous months as follows:

| | October, Pounds. | September, Pounds. | August, Pounds. |
|-----------------------|---------------------|-----------------------|--------------------|
| Stocks | 151,472,772 | 135,632,565 | 122,596,607 |
| Production | 124,657,709 | 118,023,139 | 120,597,234 |
| Total | 276,130,481 | 253,655,704 | 243,193,841 |
| Domestic deliveries . | 66,339,617 | 52,105,155 | 59,614,207 |
| Exports | 56,261,238 | 50,077,777 | 48,382,704 |
| Total consumption. | 122,620,855 | 102,182,932 | 107,996,911 |
| Stocks remaining ... | 153,509,626 | 151,472,772 | 135,196,930 |

The chief item in the Copper Producers' Association's report is the matter of surplus stock on hand, which shows an increase for the month of 2,036,854 lb., which compares favorably with the September increase of 15,840,207. Exports for October were 56,261,238; domestic deliveries, 66,359,617, the refinery output was 124,657,709 lb. The October output breaks all previous records for production for a single month. The total surplus on hand November 1 was 153,509,626 lb. When it is considered that the total surplus is only a little more than one month's production, that consumption is still running far below normal requirements, the copper surplus ought not to be the weight upon the market that it seems to be. As the matter now stands, practically all of the load is an inheritance from 1908, when the surplus on hand, as on January 1, 1909, was 122,357,260

lb. In view of the fact that the year has been one when production has been breaking records and consumption was far below ordinary requirements the surplus increase of 30,000,000 lb. is not alarming. Ordinarily it would be hardly enough to act as a safe balance wheel for the metal market. The truth is the copper surplus is an inheritance from the days of the 1907 panic, when after a runaway market and ensuing collapse, many mines were compelled to run and keep up production at a loss, because this involved less loss than to shut down and allow machinery to deteriorate and water to accumulate.

The copper combination, which has been the source of much discussion during the past few months, is evidently beginning to take definite shape. Executive officials of some of the companies to be absorbed have stated within the past few days that an agreement has been reached as to the fundamental outlines of the new financial structure. None of the gentlemen interviewed have been willing to allow the use of their names in the matter, but it may be definitely stated that the merger is to include the Amalgamated Copper Co., the Cole-Ryan properties, and the Phelps-Dodge mines, and, perhaps, the Guggenheim properties. William E. Corey, the president of the United States Steel Corporation, and the banking house of J. P. Morgan & Co., are working out the details and some definite public announcement may be expected very shortly. There is no question but the admissions made that such a combination is well under way have already given a much better tone to the metal market. Some large buyers are quoted as being actively in the market for copper at present figures, anticipating an advance.

The more important copper shares in the market have been noticeably stronger during the week, Nevada Consolidated being the leader and selling between \$27 and \$28. Among the cheaper copper stocks, especially the Ely stocks, led by Ely Central, there has been a wild market. The excitement was started by an attack in the columns of the press upon the house which has been carrying on a spectacular advertising campaign, booming the shares of the Ely Central Copper Co. Overnight the shares dropped from above \$4 to a low point of \$1 before the market steadied. It is not thought that the movement in this particular issue can gain headway after the setback it has received and the bitter personal attack made upon some of the operators engaged therein, with regard to one of whom prison records were dug up and published. The market activity in Ely shares has noticeably subsided. It has been, on the whole, rather unfortunate for the market, that shares in these properties should have been made the vehicle of active speculation. The successful mines at Ely are conducted as are immense factory plants, and such startling developments as made the Comstock its place in history, and, later, made Goldfield the centre of excitement, are by the nature of the deposits impossible. Ely properties, when the necessary millions and the equally necessary engineering and metallurgical talent and brains are added, are investments, with great possibilities for appreciation in value, but they are not speculations, such as can justify any such extravagant market movements as have been recently carried on in New York in these shares.

The Goldfield stocks are, seemingly, wholly neglected by the public, the publication of the report of Goldfield Consolidated, which shows it to be earning a moderate surplus over its dividend requirements, had no effect in the way of increasing activity in the shares. Cobalt stocks, although in many cases returning handsome dividends, as in the case of Crown Reserve, which has just declared a dividend of 6%, with an extra disbursement of 9, payable in January, and a cash bonus of 10, which will be distributed December 23, as a Christmas souvenir for the shareholders, are not having much support from the public in the States. A review of the mining markets and mining conditions leads to the conclusion that if the public could be induced to seek mine profits with the same avidity and persistence that it seeks market profits, it would greatly benefit both the public's pocket and the mining industry, though there would undoubtedly be some promoters compelled to seek other fields.

MEXICO.**Milling at Pachuca.—Guerrero Mill. — Hostotipaquillo. — Amparo Mine.—Nazas River Reclamation Project.**

Metallurgical methods in Pachuca, State of Hidalgo, have been revolutionized during the last few years, and anyone wishing to see the patio process at work there will have to hurry. Three large mills are in operation, the Loreto, Guerrero, and San Rafael, and a fourth, the Guadalupe, belonging to the Santa Gertrúdis company, will be in commission soon. These mills all approximate a capacity of 400 tons per day. Coarse or medium coarse crushing is followed by concentration to remove the more easily concentrated material, which happens to result in the removal of the bulk of the cyanicides. The tailing is re-ground to slime, either by single-stage tube-milling or by step-reduction. The resulting slime is agitated with cyanide, followed by vacuum filtration alone, or by decantation and vacuum filtration. Crushing is done in solution in every case, and de-watering and return is also the rule. The ore is first crushed to pass a 2-in. ring in Blake crushers, followed by stamps crushing to 12-mesh, and concentration on Wilfleys. The Wilfleys are also used as classifiers, the slime being sent direct to the Dorr pulp-thickeners. The tailing goes to Dorr classifiers, and the pulp from the Dorr classifiers to tube-mills and return, for which spiral sand-pumps are used. These are practically the only elevators in the mill. From the tube-mill to the Dorr pulp-thickeners the thickened pulp is sent to Pachuca tanks for air-agitation, followed by Moore vacuum-filtration. The solutions go to iron zinc-boxes using zinc shavings, and the precipitate to a small filter-press. The melting is done in crucibles in coke furnaces.

In the Guerrero mill, simplicity has not been considered so much as mechanical efficiency in crushing, and the careful elimination of the cyanicides by step-concentration. The general arrangement is as follows: stamps crushing to 3-mesh; to settling-cones, from which the thick pulp goes to Callow belt-screens; the oversize to Evans-Waddell Chilean mills, and undersize to 3 double-cone hydraulic classifiers; coarse sand to Wilfley tables, medium sand to another set of Wilfley, and fine sand to Johnston concentrators; the slime from the settling-cones and from the 3 hydraulic classifiers goes to a set of Callow de-watering cones, the spigot-product of which goes to Johnston concentrators adjusted for treating slime, and the tailing from these concentrators goes direct to the cyanide plant. The product of the Waddell mills, crushed to 40-mesh, goes to a settling-cone, the slime from which goes to the de-watering cone for the Johnston slime-concentrators, the spigot going to hydraulic classifiers, from which the medium sand goes to the Wilfleys, and the fine sand to the Johnston sand-concentrators. The tailing from the Wilfley tables returns to the Waddell mills; that from the Johnston sand-concentrators to the Dorr separators; the slime from these, crushed to 200-mesh, to the cyanide plant, and the pulp to the tube-mills to be re-ground. The cyanide plant consists of flat tanks with mechanical agitation, followed by decantation of the first and second solutions, succeeded by treatment in a Butters vacuum-filter. The precipitate is dried and shipped to the Loreto mill, which belongs to the same company.

The Marcus Daly interests, holding option on the Cinco Minas group in the Hostotipaquillo district of Jalisco, are now represented by T. A. Ross, who was formerly in charge of the Daly Reduction Co.'s works at Hedley, British Columbia. Mr. Ross is making a final inspection of the development work that has been pushed ahead by H. E. Crawford. A further payment has to be made on the purchase price in January. The total price is ₧530,000. Reference was made some time ago to the increase in depth to be made in the 3-compartment shaft of the Amparo Mining Co. in the Etzatlán district. The contract has been let to C. F. Joyce to sink an additional 300 ft. for \$40, United States currency, per foot, or a total of \$12,000 for the whole extension of the shaft.

Reference was made in a former letter to the Nazas river project, and it has been now decided by the Federal Government that the district is so valuable, agriculturally, as to warrant the expenditure of ₧11,000,000 to build storage

reservoirs for the equalization of the flow of the Nazas river, as by this means the available acreage that can be brought under cultivation will be enormously increased. The project includes the building of two immense reservoirs and a canal to connect the waters of a large lake, with the irrigation system of the Nazas river valley. It seems probable that S. S. Pearson & Sons will get the contract for the whole undertaking. When the project is completed it will give an immense impetus to both agriculture and business.

DENVER, COLORADO.**Cripple Creek.—Boulder Tungsten District.—Georgetown.—Colorado Springs Coal.—State Geological Survey.**

Cripple Creek furnished the usual amount of bullion for the month of October. The production amounted to \$1,291,630. As compared with the figures for September the tonnage increased 470 tons, while the value per ton dropped \$5.81. The production for November will probably be still smaller as the month is short and the snows are beginning to interfere with wagon hauling. Leases granted recently include one on the Empire State shaft and workings, one on the nine claims belonging to the Isabella Mines Co., to the Western Investment Co., of Victor, and the properties of the Republic Gold Mining Co., on Beacon hill, to Sherman Bell. Four mining corporations operating in the district distributed dividends in October amounting to \$154,000. These were the Portland Gold Mining Co., 2c. per share, \$60,000; the Vindicator Consolidated Gold Mining Co., 3c. per share, \$45,000; the Elkton Consolidated Mining & Milling Co., 1½c. per share, \$12,500. The Deep Drainage tunnel advanced 380 ft. during October, making a total of 11,400 ft. from the portal with 3250 ft. yet to go before reaching the main water course. Shippers of low-grade ore to the United States Reduction & Refining Co., at Colorado City, have been notified of a reduction of 50c. per ton on \$10 ore, making the freight and treatment charge \$4 on this ore. The tungsten mines, in the Boulder district, are producing heavily since the rise in the price of the ore, due to the increased steel business. A new tungsten district is being opened near Rollinsville, in the northern part of Gilpin county. Shipments are to be expected in the early spring. The mine operators near Boulder are trying to arrange for a modern cyanide mill at that place to treat the telluride ores of the district. Several important transfers of property in the vicinity of Georgetown have occurred lately. The Bellevue-Hudson and Anamosa group of 14 lode claims situated on Columbian mountain has been sold to Southwestern Mines company, of Boston, for \$63,500. The company has a small force of men working and machinery on the way for shaft-sinking and development work. The Belmont group of nine claims on Saxon mountain has been transferred by the Krupp Mining & Milling Co. to W. L. Mallernee, formerly of Austin, Nevada. The old Dumont mine and mill, near Central City, has been leased by the E. S. James Mining & Milling Co. The lessee is driving an adit to drain the property to a depth of 1000 ft., and is making some repairs to the 10-stamp mill. The high price demanded for an inferior grade of coal by the coal dealers' combine in Colorado Springs, has stimulated competition in the local field. The Colorado Springs Electric Co. has arranged to prospect by drilling its coal lands north of the city with the idea of producing its own fuel. Local men, backed by outside capital, have secured a six months' option on about 5000 acres belonging to the Palmer estate. The land is situated north and east of the city, along the Rock Island railroad, and is within the known coal area.

Back in 1872 the territorial legislature of Colorado created the office of State Geologist. The incumbent was to serve for a period of two years without remuneration of any kind from the State. Although public-spirited geologists of high standing have held the office from time to time, the State has accumulated little in the way of reports. The Sixteenth General Assembly appropriated \$5000 for salaries and expenses, thus, in a slight degree, relieving the State Geologist from his embarrassing position. As a result the first report of the Colorado Geological Survey is at hand.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Two cars of sulphide ore were shipped recently from the Denn-Arizona mine in the Bisbee district to the Copper Queen smelter at Douglas. This is the first shipment for some time, but it is understood that the company is preparing to ship regularly as a large orebody is being opened on the 120-ft. level.—The Arizona & Cleveland Mining Co., owning 13 claims east of Johnson, will resume operations the latter part of this month. A number of assays of ore taken from the property have run from 5 to 78% lead, with 30 to 630 oz. silver per ton.—At the Centurion property the shaft has cut a small body of 30% copper ore and on the 125-ft. level the company is blocking out ore that assays about 5%. J. P. Richardson is manager.—The Keystone Mining Co., at Johnson, has cut some good ore in the shaft and is preparing to install compressing and hoisting machinery.—The Pawnee Mining Co. has been incorporated at Douglas to operate the Claire claims in the Paradise district. Considerable surface work has been done at the property and several shipments of lead-silver made to the smelter.

GILA COUNTY.

Two new Star churn-drills have been ordered by the Warrior Development Co., and will be installed at its property in the Miami district. Both the raise on the 300-ft. intermediate level and the drift have been in high-grade ore during the past week.—The Boston-Miami Development Co. has installed a churn-drill at its property near Miami and will block out the ground in 200-ft. squares.—At the Live Oak mine the west drift on the 200-ft. level is in ore averaging 2¼% copper and the north drift 2½% ore.—A vein of high-grade copper ore was opened on the third level of the Gibson mine at Gibson. The winze, which was started a short time ago on the fifth level, is still in good ore.—Ore assaying \$32 per ton has been opened near the surface of the Duquesne mine, in the Gibson district, and several teams started hauling to the Old Dominion smelter. John F. Shaw is in charge of the work.

GRAHAM COUNTY.

The mill at the Gold Belt in the Morenci district was completed last week and is in operation. A pipe has been laid from the Morenci main to bring the water to the mill, and work has been started on the buildings for the power plant.—The Copper Mines Co. of America has two churn-drills on the property and will have both in operation in a few days.

CALIFORNIA.

BUTTE COUNTY.

The Cherokee Gold Gravel Co. has been organized to reopen the old Spring Valley property at Cherokee and operate it as a drift mine.

CALAVERAS COUNTY.

The cyanide plant at the Sheep Ranch mine, at Sheep Ranch, has been closed down for the winter.—The débris dam of the Cave City company has been completed and the ditches and tail-race are being put in order for the coming hydraulic season.—The shaft at the Clothier mine, near Copperopolis, has been unwatered and will be sunk an additional 200 ft. A new hoist will be erected and considerable development started.—The Duck Bar mine has been closed for the winter.

EL DORADO COUNTY.

The 10-stamp mill at the Mount Pleasant mine, at Grizzly Flat, was started on a lot of ore from the 300-ft. level.—At the Morey mine the mill is running on ore assaying \$100 per ton.—The Noble Metals Recovery Co. has secured a two years' lease on the Golden Cup claims in the Greenwood district.

INYO COUNTY.

The Bishop Creek Gold Co. has completed the installation of a Sullivan 9-drill compressor, and has started drifts on

the vein at the second level at a depth of 288 ft. J. S. Chapman is superintendent.—The water jackets on the furnace at the smelter at Keeler have been replaced by new ones and new buckets and grips are being placed on the tram, the old ones having proved too light. The repairs will be completed about the first part of December, and the smelter blown-in again. A consolidation is being effected between the Four Metals and the Great Western companies.—The shaft at the Union mine is down 1025 ft., and a large amount of zinc ore stored on the dump. The company will store all ore till a spur is completed to the smelter.—An extremely rich discovery has been made at Burgess, a new camp in the Inyo mountains, east of Lone Pine. A 3-ft. vein of high-grade ore has been cut at a depth of 93 ft. causing a rush of prospectors to the district.

MONO COUNTY.

(Special Correspondence).—The Standard Consolidated Co. has decided to lease its holdings, outside of the main workings, and several applications will be granted within a few weeks. Work in the main levels will continue on company account, and it is reported that the installation of powerful electric pumps to unwater the mine below the 600-ft. level will commence early next year. The mill is running steadily on fair-grade ore from the upper levels.—The Douglass company has opened a \$30 shoot of ore on the Mary claim, in the Gold Range district which is said to be over two feet wide. Ten stamps are dropping in the mill.—J. H. McCormick, understood to represent the Broken Hills Mining Co., has closed a deal for the Parret mine, the reputed price being \$300,000. The property is near the May Lundy but has not been developed to any extent. Several small stringers of rich ore and three large veins are said to be uncovered assaying from \$8 to \$300 per ton.—Considerable prospecting is going on in the Mono Lake district and several important discoveries of gold have been recently reported.

Bodie, November 15.

NEVADA COUNTY.

(Special Correspondence).—Considerable work is going on below the 3000-ft. level in the Empire. It is stated that the sinking of the shaft will commence as soon as the running of the big cross-cut near the 3200-ft. level has been completed.—Operations below the 4000-ft. level in the North Star mines are being attended with good results. It is understood that operations at the Massachusetts Hill mine will be resumed next year. The 80-stamp mill is treating ore at a total milling cost of about 80c. per ton.—The 3-compartment shaft at the Brunswick is making slow progress, owing to the hard formation and presence of water. An ejector has been installed and the compressor is about to start. A small force of men is working.—It is reported that sinking will be soon resumed at the Prudential, formerly the New York-Grass Valley. A. P. Wilson is manager.—The San Francisco people who recently took over the Lincoln mine have decided to expend \$10,000 in underground development. The shaft will be deepened and much lateral work undertaken.—Sinking to the 600-ft. level in the Central is progressing, and from this point a long drift will be driven. C. N. Bailey is manager.—It is rumored that operations will shortly be resumed at the Murchie. Part of the indebtedness has been defrayed, and the pumps have been kept in constant action since the suspension of activities.—The Mooney Flat claim is being actively developed.—Sinking at the Kenosha continues steadily. The shaft will be sent to the 800-ft. level. On the 300 and 400-ft. levels milling ore is being opened and occasional bunches of high-grade quartz cut. George W. Root is manager.

Grass Valley, November 17.

A new compressor has been installed at the lower adit at the Gaston mine. In the mill 15 stamps are dropping on ore from the upper levels.—The final payment has been made on the Lincoln mine on Deer creek by John R. Tyrrell and Percy Waters.

PLUMAS COUNTY.

Operations have been temporarily suspended at the Great Divide Mining Co.'s property, in the Indian Valley district.

on account of the shortage of water. The gravel is near the summit of a ridge, all the wash water being pumped from the ravine below. Work will be resumed in the spring with increased pumping facilities.

SAN BERNARDINO COUNTY.

(Special Correspondence).—The new 100-ton leaching plant of the California Gold & Copper Co. is rapidly nearing completion, and it is expected to commence the production of copper within 60 days. Large quantities of oxide and carbonate ore are available in addition to the sulphide reserves opened in the lower levels. Three shafts have been sunk, the deepest being down 325 ft. A. H. Cram is manager.—Promising ore has been intersected on the X-Ray.—The Iron Chief Mining Co. has commenced work on the Eagle Mountain iron deposits. L. S. Barnes is manager.—Considerable work is going on in the tungsten properties in the Clark mountains, 16 miles northwest of Ivanpah. The rocks of the district are principally granite and limestone. The Mount Clark, Hamburg, Jack, Tungstine, and Fitzpatrick, are among the best claims in the district.

San Bernardino, November 15.

SHASTA COUNTY.

The new tramway for the Holt & Gregg quarry, which furnishes limestone for the smelters near Kennett, is nearly completed and will be in operation next week. New tracks are also being laid at the quarries and when completed the output can be raised to 500 tons per day.—It is under-

stood that the Balaklala company is to build a bag-house at its smelter at Coram, but no date has been set for beginning the work.

SIERRA COUNTY.

At the Hunch mine, in the Alleghany district, a new adit is to be started to open the vein at a depth of 200 ft. The former adit cut a 4-ft. vein when in 231 ft., giving 85 ft. of backs.—A lot of high-grade ore from the Sixteen-to-One mine, at Alleghany, was run through the Oustomah mill near Nevada City with excellent results.—The bedrock adit at the Hilda mine, near Sierra City, cut the channel and the owners are doing considerable work to prove its value. The gravel that is now being taken out runs from \$3 to \$12 per car.—The force at the Chipps mine has been increased, and 12 stamps are dropping in the mill.—At the Bullion property a pocket of ore assaying over \$200 per ton was opened.—The Rip Saw mine has been closed down for the winter.—The raise at the Hilo mine, on Chaparral hill, has been completed and the workings are now well ventilated.—Drilling at the Tobacco Flat property has been stopped for the winter. The hole is down 160 ft. in the lava capping.—The gasoline engine has been installed in the mill at the Oakland mine, but the building has not been completed so there will not be much ore crushed this winter.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The past week has been a busy one in the Georgetown district. Numerous mines that

have been lying dormant for a long time are to again receive active development. After a shut-down of over a year a force of 15 men is being employed at the East Griffith, on Griffith mountain. Large development is to follow, as the Griffith Mines Co. is to furnish the heaviest tonnage for the chemical-electric plant in course of construction by the Western Metals Co. W. D. Hoover, of Denver, is manager.—Work was resumed at the Vidler adit in East Argentine, Charles Hall having been awarded a contract for the driving of the bore several hundred feet.—C. E. Pughe, manager for the Linn Consolidated Mining & Milling Co., operating the Mineral Chief mine, on Democrat mountain, has agreed to supply a portion of ore for the chemical-electro plant, adding to the working force.—William M. Cooper, manager for the Capital Mining & Tunnel Co., is constructing an electric line from the United Hydro Power & Electric Co. plant, with which to secure additional power at the 150-ton mill. An addition to the building is in the course of construction. Additional tables have been ordered and it is stated that from 150 to 170 tons of ore will be treated each day.

Georgetown, November 15.

(Special Correspondence).—A contract has been awarded by the Great Northern Mines Co. to drive the 100-ft. adit on the Elm City vein for an extra 100 ft.—A 6-in. streak of ore was intersected on the Bronaber vein last week that assays 1.08 oz. gold. J. T. Mallalieu is manager.—The Tanguay Mining Co. is employing a large force of men at the Josephine mine and shipments of smelting ore have been started. The old Lincoln mill has been overhauled and new machinery purchased. The concentrate so far marketed has exceeded \$25 per ton. J. H. Haynes is in charge.—During the month of October the Central tunnel was driven 96 ft., making the total length 7815 ft. A number of mines are being operated through this bore, the principal of which are the Shafter, Edgar, and Miami.—A pool of local business men has secured control of the Stanley placer and work on a large scale is to be started. A 35-hp. boiler, hoist, and pump have been purchased and are now being placed in position.—A rich find has just been made on the Chicago Belle property at Dumont.

Idaho Springs, November 15.

GILPIN COUNTY.

(Special Correspondence).—A night force has been put on at the Freedom shaft on Winnebago hill, and the workings are being re-timbered and cleaned, preparatory to starting an extensive campaign of development. Large bodies of medium-grade ore are said to be exposed in many of the workings and C. E. Major, the manager, expects to start shipping within from 30 to 60 days.—The Golden Flint mill, at Rollinsville, is running night and day, and during the last week a gold retort of 60 oz. was sent to the Denver mint, the result of one week's clean-up. A carload of concentrate was also sent to the Modern smelter.—A syndicate of Kansas City men has taken a bond and lease on the Susan Mary property, east of Blackhawk.—Denver parties have started work on the Dunn property in the Pine Creek district. The adit has been driven for 295 ft., and drifts run on the vein for 75 ft. New cars and rails have been purchased.—From six to eight carloads of ore are being sent out each day from the Frontenac mine in South Willis gulch, the product being taken from the fifth, sixth, and seventh levels in the west drift. Since breaking into the seventh level, Mr. Lowe, the manager, reports a much better showing. The Frontenac mill, at Blackhawk, is to be enlarged, the capacity to be increased from 75 to 100 tons per day. Card tables will be purchased.—The Aztec Mines Co. is making a number of improvements at the O. K. mine on German hill. A new shaft-house is to be constructed at once and everything placed in condition for enlarged development.

Central City, November 13.

LAKE COUNTY.

Harry Mamlock has resumed work on the Doris property at Leadville, and is repairing the surface plant.—The new Cramer mill will be completed shortly and will treat the ore from the dumps of the Morning Star and Evening Star

mines. Clausen & Buchanan, leasing the Porter shaft of the Morning Star mine, are shipping 500 tons per month.

OURAY COUNTY.

Three carloads of machinery for the smelter that the Mono-Baltic Mining & Smelting Co. is building have arrived and work will be started at once on the plant. Smith McKay will have charge of the work.—A contract has been let to drive a 129-ft. raise at the Commodore Foote property to connect the lower level with a winze that was sunk from the upper adit. The ore in the winze assayed 210 oz. silver and \$7 gold per ton.

TELLER COUNTY.

Cox, Whitmore, and associates, who recently secured a renewal of their lease on the Damon mine, have opened a new orebody on the 100-ft. level, and are shipping to the Cripple Creek mills.—Gold bars were sent to the Denver mint from the Gaylord and Gold Issue mills, approximating \$10,000 gross value. The Billiken Mining Co. has been incorporated to operate in Cripple Creek district, the first property secured being the Specimen mine, on Bull hill, which has been leased from the Stratton estate.—The Anaconda mill, on the Mary McKinney property, has been purchased by Pascal Craig and is being re-modeled to handle the low-grade ores from the properties of the Lexington Gold Mining Co.—The tenth of the month was payday in the Cripple Creek district, and it is estimated that \$350,000 was distributed.—The Doctor-Jack Pot Mining Co. has declared its quarterly dividend of $\frac{1}{2}$ c. per share, payable December 1.—The Humphreys-Thompson Syndicate has secured a lease on the Sheriff mine, on Raven hill, and will re-timber the main shaft to the 100-ft. level.—Twenty-five tons of ore shipped from the Santa Rita mine were settled for on the basis of \$56 per ton.

IDAHO.

KOOTENAI COUNTY.

Four feet of lead-copper ore, with some gold, was cut on the Idaho Copper Mining Co.'s property at Priest lake. The ore was opened by a cross-cut from the shaft at a depth of 75 ft. J. L. Lamphere is in charge of the work.—Shipments of rich copper ore are being sent from the Big Elk mine near St. Joe to the smelter at Tacoma.

OWYHEE COUNTY.

The Banner Mining Co. has added a number of men to its force and the tramway from the mine to the mill is being rapidly completed.—The high-tension line has been connected to the power house at the property of the Silver City Mining & Milling Co., near Silver City, and the plant will be in operation in a few days.

SHOSHONE COUNTY.

Wilbur D. Greenough, president of the Snowstorm Mining Co., operating in the Coeur d'Alene district, announced in Spokane that the company will pay regular monthly dividends of \$22,500.—The Silica Gold & Copper Mining company has been formed at Wallace to work a property situated on the north fork of the St. Joe river, west of the Monitor mine. Three veins have been traced across the ground and three claims are located on each vein.—A 100-ft. cross-cut from the 200-ft. level of the shaft at the property of the Butte & Coeur d'Alene Mining Co. opened a good body of lead-silver ore.—A 100-ton mill is to be constructed for the Black Horse Mining Co. at Paragon, and a tramway built from the mine to the mill.—L. C. Jaquish, who is directing the work on the Mineral Farm group, at Mullan, states that the 5 by 7-ft. cross-cut is in 1420 ft., and that the mineralized zone will probably be reached in less than 100 feet.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The last fortnight has noted the exchange of much mining property in the Joplin district. The Producers Mining Co. has bought the Nancy mine and mill in the Belville camp for a consideration of \$20,000.—In the same camp a Carthage company has purchased 120 acres north of the producing Claycomb land for \$10,000, and will go to work at once.—G. L. Babsen, of

Webb City, has bought a first lease on 10 acres of the Excelsior Lead & Zinc Co.'s land at Four Corners and work will start at once on a 150-ton plant. The price paid was \$20,000.—The Federated Mines & Milling Co. has purchased from the General Zinc & Lead Co. the old Eleven O'clock mine, and a 10-acre lease at Prosperity, the consideration being \$7000.—Among the recent finds reported is one at Duenweg adjoining the McGee silicate property. Lead ore has been discovered from 35 to 55 ft. and a shaft down to 55 ft. is just getting into a blende deposit.—A rich discovery has been made on the Sampson land near Knight's station, four holes now being in ore showing galena from 105 to 120 ft.—Northwest of Carthage a new field has been opened by Steve Chitwood, having drilled through 10 ft. of good silicate on the Wakefield farm. On an adjoining tract a fine run of zinc blende has been opened at 219 ft.—East of Joplin, on the Weyman land, what promises to be one of the best finds for a long time has been opened up by Greninger & Co. The drill first struck ore at 40 ft. continuing to 75. At 94 ft. more galena was found extending to 108, at which level zinc blende was penetrated, and the drill hole was still in ore when it stopped at 119 ft. The ore assays as high as 30%.—Another excellent discovery has been made in Tanyard Hollow at a shallow depth. The ore runs from 15 to 20% zinc and lead. A number of companies are prospecting in that locality.—Two tailing mills are to be erected in the district, one on the Knol ground at Duenweg, which will treat the waste from the old Miami, Millard, Provident, and Egyptian. A second will be built in Jackson Hollow. It will be used as a custom mill and will also treat the tailing from the hand jigs employed in that camp.—Two new mills are promised for the Riseling ground southwest of Joplin, one to be on the old Mandarin tract from which a mill was removed some time ago, and a second to replace the Live Oak which was burned. The latter lease was just getting into splendid ore at the time of the plant's destruction. At both places there are still good workable faces.—A new mill is going up on the Mercantile lease north of Webb City, making the third plant for that company. It will have a capacity of 400 tons. The two mills proved inadequate to treat the ore produced. The company has heretofore been working at the 160-ft. level, but when the plant is completed it will deepen the work to 175 ft. at which point a good sheet face has been discovered.—The Blue Pigeon mine at Tuckahoe is one of the present rich producers of the camp, the ore being cleaned on hand jigs. Much of the ore requires no treatment but occurs in large chunks.

Joplin, November 13.

MONTANA.

MISSOULA COUNTY.

The Monitor Mining Co. is to drive a 5100-ft. lower adit on its property at Saltese. This will open the ore at a depth of 2200 feet.

SILVER BOW COUNTY.

(Special Correspondence).—James H. Reed, of Pittsburg, vice-president and director of the East Butte Copper Mining Co., has been in Butte the past week, engaged in an inspection of the mines and affairs of the company, and at the conclusion of his examination he said the company and the mines were in excellent condition, and for the first time in the history of the company it is earning a good net profit. Since the Pittsmtont mines and smelter have been taken over by the East Butte company, many economies have been introduced, and extensive development carried on in the mines. The company is producing copper at the rate of 7,000,000 lb. per annum and the smelter is run only at half capacity.—The vein on the 1500-ft. level of the Colorado is being opened, which is the lowest level in the mine, but it is the intention of the management to sink the shaft 1800 ft. deep. The assays from the vein on the 1500 give an average of $3\frac{1}{2}$ % copper, and something better than 6 oz. silver per ton, which is about the same as yielded by the ore on the 1400-ft. level. Two new levels will be opened between the 1500 and 1800, which will put the mine into condition for a large production. At present all the mining is being done on the 1400, but a raise has been made from

the 1400 to the 1200 and the opening is all in ore. The company is hoisting about 150 tons of ore per day.

Butte, November 13.

NEVADA.

ESMERALDA COUNTY.

Drifts are following the Victor vein of the C. O. D. Consolidated, and the presence of gray copper is regarded as encouraging. A considerable quantity of shipping ore is exposed in the upper levels of the mine, and further shipments will be made.—The cross-cut at 220 ft. on the Cracker Jack, which is being driven by Mitchell & Fairfield, is nearing the large vein opened above the 100-ft. level.—A hoist will be in operation within a few days on the Thomas lease near the peak of Columbia mountain. Ore of high grade, and carrying free gold, has been found at 115 ft. in the shaft, and a raise will be driven to the shaft from the old company tunnel.—A shipment of high-grade ore was made lately from a lease on the Blue Bull.—William MacKay, who conducted operations on some of the bonanza Mohawk leases, is operating a lease on the Velvet claim of the Merger Mines Co., and has ore blocked.—The Stoneham-Moore-Griffiths lease has a vein of good ore at the 600-ft. level east of the shaft, and is driving for a shoot from the Florence vein.

LANDER COUNTY.

(Special Correspondence).—The Austin Manhattan has cut the Panamint vein in the Frost shaft, 85 ft. below the main adit, and driving to exploit the vein on both sides of the shaft has started. The management announces that the first unit of 10 stamps will be installed within 60 days. The equipment includes a Chilean mill for re-grinding, cone classifiers, Card tables, tube-mill, cyanide tanks, and Merrill filters. C. W. Merrill, of San Francisco, will have charge of the installation. W. W. Wishon is general manager.—The King Midas has struck a strong vein of gold quartz assaying \$40 to \$50 per ton.—It is rumored that the Nevada Equity will erect a mill early next year.—A rich deposit of silver-lead ore has been discovered in the Battle Mountain district.

Austin, November 13.

NYE COUNTY.

(Special Correspondence).—The output of the Round Mountain mill for October amounted to \$41,000. Two ore-bodies, believed to be new veins, have been opened on the 600 and 700-ft. levels. On the 600 the vein is 16 ft. wide, and assays are said to run \$10 to \$15 per ton. It is probable that operations on the eastern portion of the property will soon commence with churn-drills. It is rumored that the directors are considering the declaration of an extra dividend for Christmas. James R. Davis is manager.—The Toquima mill has resumed operations and about 30 tons of ore are treated daily. Within a short time it is expected to handle 50 tons per day. The company has secured a good supply of water.—The owners of the Round Mountain Sphinx and Round Mountain Red Top groups have filed a citation in the district court charging the Round Mountain Mining Co. with extracting ore from properties of plaintiffs.—The Crown Point Globe company, at Johnnie, has decided to install either a 5 or 10-stamp mill. Good results have been secured with the 1-stamp plant, but its capacity is far from sufficient for the ore developed. The company holdings will be patented and a larger pipe-line installed.—The Nevada Johnnie has opened a 4-ft. vein of \$20 ore on the Bullfrog Johnnie. It is reported that this company will install a 5-stamp mill next spring.—The shaft at the Buckeye-Tonopah is down 800 ft., and is passing through rock carrying considerable water. The equipment of the Little Florence at Goldfield has been purchased and will be erected at the Buckeye immediately.

Round Mountain, November 13.

WHITE PINE COUNTY.

The grade from the branch line of the Giroux company's railroad to connect the new shaft with the Nevada Northern tracks will be completed about the first of the year, and coal bunkers and water tanks constructed at an early date. The track will be standard gauge and 90-lb. rail will be used in the construction.—It is reported that the Cole-Ryan interests have secured an option on the controlling interest

of the stock of the Federal Ely company. Deeds have just been placed on file conveying the properties of the Veteran-Ely Extension Mining Co., and the Rickard-Ely Mining Co., to Thomas F. Cole.

OREGON.

GRANT COUNTY.

(Special Correspondence).—The mill at the Cougar mine, three miles from Granite, which is being operated by the National Mining & Leasing Co., has been re-modeled under the direction of Algernon Del Mar, and an all-slime process installed. The ore goes through a jaw-crusher, rolls, and Hardinge conical mill to the agitation tanks. The vein is between 3 and 4 ft. wide, and the average assay of 47 samples was \$17 gold per ton. Theodore L. Lammers is manager.

Granite, November 15.

TEXAS.

BREWSTER COUNTY.

(Special Correspondence).—S. H. Webb, of San Antonio, and associates, are developing a quicksilver claim in the Rosillas mountains, in the southeastern part of the county, and have met with such encouraging results that a 20-ton furnace will be installed. It is stated that the cinnabar ore runs high in quicksilver, and that enough ore is now in sight to keep the proposed furnace in operation for some time. The mine is some distance from Terlingua, which is the centre of the older quicksilver district. Discoveries of rich cinnabar ore are also reported across the Rio Grande, in Mexico, though so far as known but little has been done toward the development of the claims.—A syndicate of Chicago men, headed by C. W. Swenson, have taken the preliminary steps to build a railroad through the heart of the Davis mountains, the proposed line to run from Pecos to either Alpine or Marfa, a distance of about 100 miles. The building of this line will open to development one of the richest mineral regions in the Southwest, according to the report of the State Mineral Survey made a few years ago. The Davis mountains have been exploited very little for precious minerals, owing to their isolation, but a number of good claims have been located and are awaiting the building of a railroad in order to begin development work.

Terlingua, November 12.

EL PASO COUNTY.

A. D. Hudson, of El Paso, is developing a large turquoise deposit in the foothills of the Sierra Diablo, four miles from Van Horn. The country rock in which the turquoise occurs in bunches and seams, also carries more or less gold. It is claimed that this Texas turquoise is equal to that of the best mines in this country.

UTAH.

SALT LAKE COUNTY.

(Special Correspondence).—On Monday of this week the first session of the Salt Lake Stock & Mining Exchange was held in their new quarters, on Exchange Place and Cactus street. The mining temple is a handsome structure, and has been completed at a cost of \$80,000. It is situated in the heart of the new business district of the city, the ground being donated by Samuel Newhouse. The old quarters were occupied by the exchange for 12 years, and during that time the business has grown from a few thousand dollars per month to from \$2,000,000 to \$3,000,000. Seats formerly sold for \$10 and now \$2500 is being paid for the privileges of membership.—Copper production from the Utah mines for the month of October amounted to 9,750,000 lb., being a reduction of almost 1,000,000 lb. from the preceding month. The large Bingham properties mined the usual tonnage, and the loss comes from some of the smaller mines in the outlying districts.—Utah Copper keeps up its splendid production. Its quarterly report, just issued, shows the net profits from mining and milling operations for the September quarter to be \$715,586, and the additional sum of \$6095 from other sources, makes a total net profit of \$721,683. The tonnage milled during the third quarter was greater by about 100 tons per day than for the preceding one. A higher percentage of copper was also recovered which gave a grand total increased production during this period of 1,525,262 lb. The average cost was 8.077c. per lb., as against

9.192c. for the second quarter. Considering the results of the Garfield plant by itself, the cost of net copper production per pound was 7.67c. The cost of mining and milling was reduced 9c. per ton of ore, and the actual cost of milling at the Garfield plant was slightly in excess of 47c. per ton. The cost of mining and expense incident thereto at the mine was 15.39c. per ton.

Salt Lake, November 13.

WASHINGTON.
STEVENS COUNTY.

The Treadwell mine, between Northport and Ione, will begin shipping this fall. The vein was cut at a depth of 252 ft., and assays of picked samples ran from 60 to 80% lead. —Fourteen inches of silver chloride was opened by a surface cut on the property of the International Mining & Milling Co., and a test carload of the ore will be shipped.

CANADA.
BRITISH COLUMBIA.

The ore shipments from the Rossland district for the week ended November 6, and for the year to that date, were as follows:

| | Week. | Year. |
|-----------------------|-------|---------|
| Centre Star group.. | 4220 | 155,133 |
| Le Roi mine | 455 | 8,680 |
| Le Roi No. 2, Ltd.... | 532 | 25,594 |

The Le Roi mine is sending a small tonnage each week to the Consolidated smelter at Trail. This ore is a little better than the average grade of Rossland ore, which is about \$12 to \$14 per ton. Development work is being carried on in the lower levels where the diamond-drills have pierced some good ore, but in small bodies.—At the Le Roi No. 2, Ltd., the main shaft on the Josie property is now down to a point between the 1200 and 1300-ft. levels, and sinking will be continued to the 1300-ft. level before an attempt is made to open the orebodies cut by diamond-drills some months ago.—The ore shipments and ore milled in the Nelson district for the week ended November 6, and for the year to that date were as follows:

| | Week. | Year. |
|------------------------------|-------|--------|
| Blue Bell (milled) | 900 | 43,268 |
| Cork | 22 | 470 |
| Enterprise | 28 | 28 |
| Granite-Poorman | 28 | 294 |
| Granite-Poorman (milled) .. | 250 | 10,418 |
| Kootenay Bell (milled) | 70 | 2,943 |
| Nugget (milled) | 110 | 5,483 |
| North Star | 172 | 1,800 |
| Queen | 30 | 478 |
| Ruth | 120 | 978 |
| St. Eugene | 167 | 17,942 |
| Silver King | 163 | 2,764 |
| Second Relief (milled) | 145 | 6,366 |
| Van-Roi | 20 | 1,095 |
| Whitewater | 59 | 1,244 |
| Whitewater Deep (milled) .. | 700 | 31,600 |
| Yankee Girl | 25 | 1,767 |

The ore shipments from the Phoenix district for the week ended November 6, and for the year to that date, were as follows:

| | Week. | Year. |
|----------------------|--------|---------|
| Granby mines | 25,765 | 853,147 |
| Snowshoe group | 5,710 | 127,714 |
| Mother Lode | 11,264 | 254,028 |
| Oro Denoro | 750 | 5,880 |

A force of 75 men has been put to work by the railway contractors on the new line from Phoenix to Wellington. This crew will shortly be augmented by about 300 men. —The B. C. Copper Co. has a considerable quantity of ore awaiting shipment at its Wellington mines. The B. C. Copper Co. and the New Dominion Copper Co. are gradually

drawing closer together. The president and vice-president of the former have been elected to the directorate of the latter, while A. Lewisohn, a leading figure in the General Development Co., of New York, and a large stockholder in the New Dominion Co., has been given a seat on the B. C. Copper board. Arrangements are to be made for the smelting company to buy New Dominion ore when the mines of the latter start up.

Rossland, November 13.

QUEBEC.

Several veins of asbestos have been opened by a cross-cut on the 400-ft. level of the Black Lake Chrome & Asbestos Co. The cross-cut was being driven through a serpentine formation to explore a deposit of chromic iron ore, and opened the veins, which are about 1½ in. thick, the fibre being remarkably flexible.

MEXICO.
JALISCO.

The 30-ton reduction plant in the Mascota district, constructed by the Lawson Development Co., of which Thomas W. Lawson was the leading figure, is to be dismantled and

Red Mountain, Rossland.

sold. The plant was designed to treat the cinnabar of the district, but custom ores were hard to obtain and the head men of the company refused to raise the money to open the prospects, so the venture has resulted in a failure.

MICHOACAN.

The Anganguero mines of the Michoacan Railway & Mining Co., in Michoacan, have been leased to the A. S. & R. Co., and are now furnishing the main supply of iron sulphide ores coming from the plateau of central Mexico.

OAXACA.

(Special Correspondence).—The Boston-Oaxaca property, El Placer, sold by the receiver recently, was bid in by the minority shareholders. W. S. Mann has gone to Boston to purchase additional machinery.—The new mill of the Rio Seco Mining Co., started on schedule time, and has sent in the first clean-up. The management is entirely satisfied with the results.—Work was started on the erection of a new mill for the Soledad Mining Co., in Totolapam district. It will have ten 1250-lb. stamps, with tube-mill and cyanide annex.—E. M. Lawton has purchased extensive onyx deposits near Etla, and has started developing same. A. G. Hamm is in charge of the work, and a core-drill has been received, with which to thoroughly prospect the property purchased. The Etla onyx is the most popular of all Mexican onyx, on account of its great variety of colors.—The Humboldt Mining Co., of Boston, Massachusetts, has taken over the properties of the Commonwealth Mining Co., in the Taviche district.—The Colonial Mining Co., which has been doing development work on the Sierra Juarez properties, is now about ready to build a mill. The intention is to commence the erection of same this winter. The mill will contain 8 Nissen stamps with tube-mill and cyanide annex.

Oaxaca, November 12.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. A. SCOTT is at Spokane.
C. S. HERZIG is at Ray, Arizona.
A. D. FOOTE is in San Francisco.
BAILEY WILLIS is going to London.
CARL EILERS has been at San Francisco.
R. A. F. PENBOSE, JR., has been at Chicago.
A. G. KIRBY was in San Francisco recently.
HOWARD D. SMITH is in the south of France.
DAVID T. DAY visited San Francisco this week.
GEORGE OTIS SMITH has returned to Washington.
C. M. FASSETT, of Spokane, is on a trip to New York.
GEORGE B. STARR was in San Francisco on his way East.
ARTHUR WINSLOW passed through San Francisco this week.

WALDEMAR LINDGREN has returned to Washington from the West.

O. H. PACKER has returned to San Francisco from Nevada county, California.

WAYLAND H. YOUNG, of Oakland, is on professional business at La Buro, Mexico.

O. B. PERBY passed through San Francisco on his way from Alaska to New York.

REIJI KANDA sailed from San Francisco on the steamer *China* for Tokyo this week.

T. L. LAMMERS, of Spokane, is superintending work at the Cougar mine, near Granite, Oregon.

F. M. FIELD, formerly constructing engineer of the Tonopah Extension mill, has gone to Ogden, Utah.

JOSEPH LANCASTER, of Spokane, is consulting engineer for the Oriole Mining Co., operating at Metaline, Washington.

A. S. HASKELL has established offices as consulting metallurgist and mining engineer in the Foxcroft building, San Francisco.

C. K. LEITH and party have returned from the Hudson Bay region. Some anxiety has been felt over the delay in the return of the party.

JOSEPH A. HOLMES addressed the miners in the anthracite district of Pennsylvania during the week of November 8 on the use of explosives.

C. W. HAYES is a member of the committee appointed by the National Geographic Society to examine the records of the Cook North Pole expedition.

H. G. MORRIS has resigned as superintendent of the Florance mill at Goldfield to accept a position with a New York syndicate operating in California and Mexico.

S. E. BRETHERTON is now in Culiacan, Sinaloa, Mexico, where he went to start a bismuth-lead reduction plant. He expects to return to San Francisco about December 1.

CARLOS W. VAN LAW has resigned as consulting engineer for the American Smelting & Refining Co., and has accepted a similar position with the United States Smelting, Refining & Mining Company.

L. R. BUDROW, formerly manager for the Michoacan Railway & Mining Co., Anganguo, Michoacan, has been appointed manager for the Tigre Mining Co., operating the Lucky Tiger in northern Sonora.

G. S. SIMPSON, vice-president of the Butters Patent Vacuum Filter Co., will hereafter divide his time between the London and New York offices of the company. E. H. GARTHWAITE succeeds Mr. Simpson as vice-president at San Francisco.

Obituary.

E. E. HENDRICK, president of the Hendrick Manufacturing Co., died October 25 at his home at Carbondale, Pennsylvania.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING PARTNERSHIP.

A mining partnership was held to exist between persons who expressly agreed that they would hold and work certain mining claims for their joint use and benefit, and where some work was done on the claim pursuant to such agreement.

Holdt v. Hazard, (Cal.) 102 Pac. 540, Apr. '09.

LOCATION OF MINING CLAIM—QUALIFICATION OF LOCATOR.

Private persons in actions between themselves where the United States is not interested and is not a party, can not question the qualification of a locator of a mining claim, so far as its validity is affected, by reason of his being a foreigner.

Holdt v. Hazard, (Cal.) 102 Pac. 540, Apr. '09.

LOCATION OF MINING CLAIM—ACTUAL POSSESSION.

Where persons make a valid location of a mining claim on the public domain, and in accordance with the United States statutes, their right of possession will continue until they have, in fact, abandoned or forfeited the claim by failure to do the required amount of work within the prescribed time, they are not required to keep an actual possession of the claim.

Holdt v. Hazard, (Cal.) 102 Pac. 540, Apr. '09.

LOCATION OF MINING CLAIMS—MARKING BOUNDARY.

Where notices were duly posted upon each of several mining claims located on the public lands, and which notices designated the place of posting as the starting point, and where they contained calls and distances to certain stakes at the four corners of each claim, the area of which was 600 by 1500 ft., and the stakes thus called for were set, and in some instances stones were piled around them, this was said to be a sufficient marking of the claims.

Holdt v. Hazard, (Cal.) 102 Pac. 540, Apr. '09.

SALE OF MINING CLAIM—TITLE.

A patentee of a mining claim contracted to sell the same to a third person, but on the day thereafter, he executed a deed, absolute in form, conveying the claim to a corporation, without any reference to the contract. Thereafter a third person purchased the claim from the corporation without any knowledge at the time of any equitable claim of such other person arising out of the contract. In an action to settle the title to such claim, it was said that the contract and deed could not be regarded as contemporaneous instruments, because, first, they were not between the same parties, and second, because there was no connection between the rights accruing to the parties, and the purchaser from the corporation acquired title free from any equities arising under the contract.

San Domingo Gold Min. Co. v. Grand Pacific Gold Min. Co., (Cal.) 102 Pac. 548, June '09.

LEASE OF MINERALS—CONSTRUCTION.

A land owner leased to another the right and privilege of prospecting for coal, oil, or other minerals, and the right to dig, excavate, and bore for the same, and to remove them if found in paying quantities. Oil had been discovered in the vicinity, and two wells had been put down on the premises, and the existence of coal was well known. Some of the wells dug produced oil in paying quantities, and the additional compensation was paid and the prospecting was continued for several years, but 15 years after the execution of the lease, the premises were abandoned. No mines were opened for coal, and no use was made of the premises except for the purpose of prospecting and pumping oil. After the premises were conveyed, subject to such lease, in a controversy between the lessee and the grantee, it was held to be a lease for oil, gas, and salt purposes, and not a deed conveying, in fee simple, the minerals under the land.

McMillan v. Titus, (Pa.) 72 Atl. 240, Jan. '09.

Gold, Silver, and Platinum in California in 1908.

The United States Geological Survey reports that in 1908 California produced \$18,761,559 in gold; 1,647,278 oz. of silver, valued at \$873,057; and 706 oz. of refined platinum, valued at \$13,414. This platinum was all produced at placer mines in Butte, Humboldt, Siskiyou, Trinity, Calaveras, Sacramento, and Del Norte counties, three-fourths of it having been mined in Butte county.

California's output of gold, silver, and platinum in 1907 amounted to \$16,727,928, \$751,646, and \$8900, respectively. The quantity of silver mined in the State in 1907 was 1,138,858 oz.; the quantity of platinum mined was 300 oz. The record of the State's production of these metals in 1908 therefore shows considerable gains over the production in 1907. The value of the gold produced in the State in 1905 was slightly in excess of the value for 1908, but with that exception the figures for gold and silver production in 1908 are the largest attained within the last decade. The production of gold and silver by counties is shown in the following table:

| County. | Gold | Silver. | |
|--------------------------|--------------|-----------|-----------|
| | (value). | Fine oz. | Value. |
| Amador | \$1,876,174 | 24,980 | \$13,239 |
| Butte | 3,139,398 | 23,978 | 12,708 |
| Calaveras | 1,378,511 | 118,353 | 62,727 |
| Colusa | 578 | 11 | 6 |
| Del Norte | 3,488 | 36 | 19 |
| Eldorado | 342,033 | 10,385 | 5,504 |
| Fresno | 1,054 | 21 | 11 |
| Humboldt | 33,066 | 613 | 325 |
| Imperial | 5,848 | 232 | 123 |
| Inyo | 308,873 | 58,302 | 30,900 |
| Kern | 827,087 | 182,170 | 96,550 |
| Lassen | 7,284 | 1,477 | 783 |
| Madera | 45,107 | 2,385 | 1,264 |
| Mariposa | 439,862 | 8,928 | 4,732 |
| Merced and Stanislaus... | 182,970 | 2,257 | 1,196 |
| Mono | 413,946 | 49,310 | 26,134 |
| Monterey | 1,318 | 17 | 9 |
| Nevada | 2,297,963 | 41,347 | 21,914 |
| Placer | 358,096 | 4,139 | 2,194 |
| Plumas | 254,737 | 6,717 | 3,560 |
| Riverside | 5,884 | 211 | 112 |
| Sacramento | 1,166,055 | 3,058 | 1,621 |
| San Bernardino | 180,511 | 67,366 | 35,704 |
| San Diego | 6,920 | 162 | 86 |
| Shasta | 1,131,832 | 976,596 | 517,596 |
| Sierra | 412,626 | 3,617 | 1,917 |
| Siskiyou | 504,156 | 11,557 | 6,125 |
| Trinity | 602,944 | 8,055 | 4,269 |
| Tuolumne | 799,752 | 22,136 | 11,732 |
| Yuba | 2,034,486 | 18,862 | 9,997 |
| | \$18,761,559 | 1,647,278 | \$837,057 |

Gains over 1907 in the production of gold were made by 21 counties, chiefly Butte, Calaveras, Inyo, Merced and Stanislaus, Mariposa, Nevada, Sacramento, Shasta, Siskiyou, and Yuba, and gains in the production of both gold and silver were made by 17 counties, among which were Butte, Calaveras, Eldorado, Nevada, Plumas, San Bernardino, Shasta, Siskiyou, Trinity, and Yuba.

Tungsten.

The production of tungsten in the United States, according to the United States Geological Survey, is not large, as a little of it goes a long way for some of its most important uses. Since by far the largest part of the tungsten produced is used in making tool steel, the demand for tungsten decreased greatly during the recent depression in the steel industry. In 1908 the domestic production of tungsten ore, reduced to an equivalent of ore carrying 60% of tungstic trioxide (WO₃) the ordinary commercial basis in the United States, was 671 short tons, valued at \$229,955, as against 1640 tons, valued at \$890,048 in 1907. The statistics at present available from foreign countries show a similar decline.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ELECTRICITY EXPLAINED. By J. Calvin S. Tompkins. 5 by 7, pp. 64, ill. Cochrane Pub. Co., New York, 1909. Price \$1.

A useful little book which makes some things clear, but in general requires close attention on the part of the non-technical reader.

THE MINERAL INDUSTRY OF TASMANIA. Compiled by W. H. Wallace. Report for the quarter ending June 30. Pp. 16. Tasmania, 1909.

The total value of the mineral output for the quarter was £411,635. The principal items were: blister copper, 2199 tons, £148,544; tin ore, 1132.32 tons, £102,731; silver-lead ore, 20,821.26 tons, £82,790; gold, 12,449.25 oz. fine, £52,881. Dividends for the quarter amounted to £117,441, of which £105,000 came from copper mines.

COMPARATIVE STATISTICS OF LEAD, COPPER, SPELTER, TIN, ALUMINUM, NICKEL, QUICKSILVER, AND SILVER. 15th Ann. Issue. Pp. xxxix and 111. Frankfort on the Main, 1909.

These statistics are now issued jointly by the Metallgesellschaft, the Metallurgischen Gesellschaft A-G, and the Berg- und Metallbank Aktiengesellschaft. The report is distributed in this country by the American Metal Co., Ltd. The tables cover production, consumption, and prices, and are invaluable to all concerned in metal sales or purchase.

MINERAL RESOURCES OF THE PHILIPPINE ISLANDS. By W. D. Smith. Pp. 200., ill. Manila, 1909.

A general account of the distribution and production of minerals in the island, including special papers on the non-metallic minerals by Mr. Smith, the metallic by H. G. Ferguson, who also gives the statistics of production, Philippine raw cement materials by A. J. Cox, the gold-fields of Surigao Peninsula, Mindanao, by Maurice Goodman, and the production of structural material, by G. I. Adams. The report is well illustrated and is exactly the sort of a brief general account that will be most helpful.

COLORADO GEOLOGICAL SURVEY. FIRST REPORT, 1908. By R. D. George. 8vo, pp. 243, ill., index, maps. Denver, 1909.

If this report is a sample of what is to be published, Colorado has done wisely to establish a geological survey, and has fared well in its organization. The volume is not large, but its content is excellent and evidences care in preparation and conscientious field studies. The individual papers in the volume include reports on 'The Main Tungsten Area of Boulder County', by R. D. George and R. D. Crawford; 'The Montezuma Mining District of Summit County', by H. B. Patton; 'The Foothills Formation of Northern Colorado', by Junius Henderson; and 'The Hahns Peak Region, Routt County', by R. D. George and R. D. Crawford.

UNDERGROUND WATER RESOURCES OF CONNECTICUT. By H. E. Gregory, with a study of the OCCURRENCE OF WATER IN CRYSTALLINE ROCKS. By E. E. Ellis. Water Supply Paper, 232, U. S. Geol. Surv. Pp. 200. **SURFACE WATER SUPPLY OF THE UNITED STATES, PT. II., SOUTH ATLANTIC COAST AND EASTERN GULF OF MEXICO.** By M. R. Hall and R. H. Bolster. Water Supply Paper, 242. Pp. 225. **PURIFICATION OF SOME TEXTILE AND OTHER FACTORY WASTES.** By Herman Stabler and G. H. Pratt. Water Supply Paper, 235. Pp. 76.

These reports include a portion of the results of the work of the Water Resources Branch of the United States Geological Survey in the study of the streams and other sources of water supply. The particular group of bulletins illustrates the three sorts of work under way, geological studies of underground water, stream gauging, and studies in water purification.

COMPARATIVE TESTS OF RUN-OF-MINE AND BRIQUETTED COAL ON THE TORPEDO BOAT BIDDLE. By W. T. Ray and Henry Kreisinger. U. S. Geol. Surv., Bull. 403. Pp. 43. **UTILIZATION OF FUEL IN LOCOMOTIVE PRACTICE.** By W. F. M. Goss. Bull. 402. Pp. 28. **COMMERCIAL DEDUCTIONS FROM COM-**

PARISONS OF GASOLINE AND ALCOHOL TESTS ON INTERNAL-COMBUSTION ENGINES. By R. M. Strong. Bull. 392. Pp. 38. **INCIDENTAL PROBLEMS IN GAS-PRODUCER TESTS.** By R. H. Fernald, C. D. Smith, J. K. Clement, and H. A. Grine.

This group of bulletins contains concise statements of some of the results of the work of the Technologic Branch of the U. S. Geological Survey. They will be of great interest and value to all engineers interested in fuel economy.

Catalogues Received.

KEUFFEL & ESSER Co., New York. Pocket Manual of the Engineer's Solar Transit. Illustrated, 54 pages, 4½ by 6½ inches.

STROMBERG-CARLSON TEL. MFG. Co., Rochester. Bulletin No. 1000 (Revised Edition), Mine Telephones. 12 pages, illustrated, 7¾ by 10 inches.

ALLIS-CHALMERS Co., Milwaukee, Wisconsin. Bulletin No. 1618. Fighting Fires with High Pressure Streams. 20 pages, illustrated, 8 by 10½ inches.

MULCONBOY Co., Inc., 723 Arch Street, Philadelphia. Catalogue No. 19, '7-League' Leather Soled Rubber Boots and Shoes. 8 pages, illustrated, 3½ by 6 inches.

THE C. M. FASSETT Co., dealer in assayers' supplies and equipment, at Spokane, Washington, has issued a 200-page catalogue giving descriptions and prices of goods. It contains other valuable data for chemists and assayers.

KEYSTONE PLACER DRILL Co., Beaver Falls, Pennsylvania, 1909 edition of catalogue No. 4, Keystone Cable Drills for Drilling Blast Holes. Contains much valuable information for driller of holes for all purposes. Illustrated, 38 pages, 8½ by 11½ inches.

THE AVERY SCALE Co., North Milwaukee, Wisconsin. Automatic Coal Weighing. An attractive little booklet giving details of these ingenious scales which automatically determine and record net weights. They are particularly applicable to ore and coal. Illustrated, 24 pages 6 by 8½ inches.

WISCONSIN ENGINE Co., Corliss, Wisconsin, Bulletin C-4, Heavy Duty Corliss Engines, Belted type. The company in sending out this bulletin, the first of a series, says: "We have tried to include data of real service to engineers and architects, and think that the data showing the method of estimating the size of a compound engine appear in a catalogue for the first time. The edition is too limited to send out broadcast, to cranks with the catalogue collecting mania, or to the idly curious; but the bulletins will be gladly sent to anyone directly or indirectly interested in power plants and steam engineering." Illustrated, 24 pages, 7¾ by 10 inches.

Elmore Process on Tin Concentrate.

A working trial of the Elmore process on about 35 tons of tin concentrate from South Africa has just been made. The results given below are considered so highly satisfactory that a plant has just been ordered for the mine. The details are as follows:

| | S. %. | Cu. %. | As. %. | Sn. %. |
|-------------------|-------|--------|--------|--------|
| Concentrate | 1.69 | 0.26 | 2.91 | 72.38 |
| Sulphur product . | 20.77 | 2.78 | 33.00 | 3.64 |
| Product | 0.12 | 0.30 | 0.14 | 74.90 |

The loss of tin in the sulphur product amounts to only 6 lb. of tin per ton of material treated, while 95% of the total impurities have been removed. These figures show the process to be capable of such close work as to make it worthy of careful consideration.

Commercial Paragraphs.

The **HARDINGE CONICAL MILL Co.** advises that the directors of the Alaska-Yukon-Pacific Exposition have granted it the highest award given to any fine-grinding device.

WAY'S POCKET SMELTER Co., South Pasadena, California, received an award of a Gold Medal at the Alaska-Yukon-Pacific Exposition for its exhibit of a method of ore testing, as well as for the best and most attractive exhibit.

MINING AND SCIENTIFIC PRESS

"Science has no enemy save the ignorant."

EDITORIAL.

SYMPATHY from the whole world goes out to the families of the miners killed at Cherry, Illinois. The splendid heroism displayed, however, affords inspiration and some consolation.

COPPER development in Arizona is necessitating much railway building. The Southern Pacific is being extended from Courtland to Gleeson, from Tucson to Twin Buttes and Calabasas, from Globe to Miami, and from below Globe to the Copper Hill district. The Phoenix & Eastern is being built from Winkelman up the Gila valley and the Santa Fe and El Paso & Southwestern are both reputed to have additional lines planned. For most of this building, development of copper deposits furnishes the chief motive.

GOLDFIELD Consolidated, according to reports, made at the directors' meeting, November 18, earned \$5,400,000 in net profits during the fiscal year ending October 31. The total dividends declared this year, including the extra for January next, has amounted to \$4,980,662, and it is said that \$1,000,000 will remain in the treasury after these dividends are paid. Certainly the year has been a notable one for this company and Mr. J. H. Mackenzie will turn over to the new manager, Mr. J. R. Finlay, one of the world's great gold mines in excellent condition.

APOLOGIES are not easy to make except in the rare case when another's sins are discussed. All the more credit then when the matter is handsomely done. Some time since *The Financial World* in New York published a bitter attack on the MINING AND SCIENTIFIC PRESS, accusing it of having been in the pay of 'get rich quick promoters'. The editor's attention having been directed to the matter, he found that he had inadvertently named us instead of another mining paper published on the Pacific Coast. In the November 13 issue of *The Financial World* the matter is explained, and regrets expressed for the mistake. The apology is accepted in the spirit in which it is offered. Mistakes will happen in the best regulated editorial office, and stone throwing is an ungrateful occupation at best.

A GENEROUS spirit of 'live and let live' has characterized the negotiations between the Shasta County Farmers' Protective Association and the Mammoth Copper Company. An extremely interesting feature of the adjustment of the difficulties over the smelter fume that has been reached in this instance is the acceptance by both sides of the decree handed down by Judge Marshall, of the United States Circuit Court of the District of Utah. This

has all been accomplished without litigation, but in order to make the settlement definite and binding a friendly action will be brought in the competent California tribunal. The details are being worked out by Messrs T. W. H. Shanahan and Alfred Sutro, the attorneys respectively for the Farmers' Association, and for the Mammoth Copper Company. The company will accordingly complete a bag-house similar to that installed by the United States Smelting, Mining & Refining Company, at Bingham Junction, Utah, and neutralization of the sulphuric anhydride by zinc oxide will be undertaken. Another point in connection with the Utah decree, which is a part of the agreement reached in Shasta county, is that the gases issuing into the atmosphere from the bag-house flue shall not carry more than three-quarters of one per cent by volume of sulphur dioxide.

It is a matter of great interest to note that the method of neutralizing smelter fume with zinc oxide has been brought to such a state of perfection that it may be accepted as a competent solution of the problem. Whether it is subject to limitations which will prevent its becoming standard practice will appear when a description of the details is made available.

The Copper Game.

Quite the most sensible thing announced in regard to the proposed combination of the copper producers is that manufacturers will consume as much of the metal at 16 cents with assured stability of price as at 13 cents under the present conditions of an unstable market. The difficulty is to find a means for stabilizing the price without flying in the face of the Sherman Act. Combinations in restraint of trade may sometimes work a benefit, but the judgment of the world has been that commercial instruments capable of reducing economic waste too often prove destructive of individual opportunity. Rumors that the combination had been effected have been followed by denials, and public anticipation alternately has been raised and depressed. All this has been favorable to stock speculation by those who really knew the progress of the negotiations. Copper shares have gone to a high figure and now are again down. Thus the insiders have been in a position to gain from the mere anticipation of a merger, which if accomplished would probably have resulted in unloading inflated stock upon the public. The other day it was positively stated that Phelps, Dodge & Company would not enter into any combination. Thus the most alluring item was erased from the program. The Guggenheims have always stood ready to win by selling stock on the rise and metal at prices unknown to competitors, and being frequently in a position to do both, there is no wonder that a sphinx has sat by the door of J. P. Morgan & Company, the Guggenheim bankers. The latest news is that the copper magnates fear to undertake a combination until the bearing of the recent decision against the Standard Oil Company is determined. In short, the copper situation is approximately what it was six weeks ago, with no prospect of sudden change, but meanwhile the shearers on Wall Street are busy at the old trade.

Legislation and National Revenue.

Congress will be again in session soon and a general feeling exists that constructive legislation of unusual importance may be expected. It would be well if this should prove true. The mining industry has many needs, and mining men are interested in many matters that are sure to be up for action. The reform of the land laws, the support of the Geological Survey, the creation of a Bureau of Mines—these are a few. There is a feeling, too, that the time has come, if not for less talk, at least for greater performance regarding conservation. Something will likely be done; how much, depends on many factors, including the state of the public purse and the number of other demands which Congress will have to face. It should be remembered that the majority of the proposed changes require an appropriation of some sort to make them effective. Even where, as in the Forest work, the final result will be to produce revenue, the immediate effect is the reverse.

Last summer in defending himself against the charge of not having properly supported the conservation policies of Mr. Roosevelt, Mr. James A. Tawney, chairman of the House Committee on Appropriations, pointed out that we are now spending 41 per cent of our national revenue aside from postal receipts, for the army, the navy, and for fortifications; and an additional 31 per cent on account of past wars, principally in providing pensions. In other words, here in a time of peace, 72 per cent of our national revenue goes to meet war expenses, and only 28 per cent is available for all other purposes. How can we ask that additional expense be incurred for even the most useful peace purpose, unless we are willing that the war expense be cut down? It is unfair to ask the impossible of Congress.

The Federal Government has been spending money liberally and with general consent, on pensions, the army, and the navy. These expenditures must in large part continue. In addition, pressure will be brought to bear this winter to enact a law in aid of a merchant marine; perhaps partly as an auxiliary navy. Is all this necessary, and if so, is the money being economically expended? We believe it would be well to look into this thoroughly before increasing any of the war expenditures.

As to pensions, one need only visit the House at Washington on one of the evenings when such bills are considered, to discover that private pension bills are passed by hundreds with no public discussion and apparently with no consideration. Presumably they have been considered in committee, but observing the number, and knowing something of the activity of the ordinary Congressman, we have no hesitation in saying that such consideration must have been merely formal. If any one doubt this let him recall the cases of pensions which have come within his own experience; such perhaps as the leading merchant of his own town, thoroughly capable of transacting business, and in no way dependent, who may be drawing the largest pension in the village; or, possibly, a State officer, a man of private means, who is neither disabled nor dependent, and yet remains on the pension roll to the day of his death. Even

millionaires, owners of railways and mines, Governors of States, draw pensions. These are just a few cases. They indicate a distressing and wide spread moral weakness. No one has any objection to the payment of liberal pensions to needy ex-soldiers and sailors, but the plain truth is that the country went pension-mad some years ago, and the system has come to be used for political purposes.

Something may also be said as to economy in army and navy circles. The public thoroughly understands that these branches of the public service must be given latitude in making expenditures, but it requires little contact with the army, at least, to show that this latitude is abused. Furthermore, it is not generally known, yet none the less true, that the Treasury Department requires from army and navy officers less detailed statements, and less in the shape of vouchers than from men in the other departments. There is not the careful and intelligent consideration of small expenditures in these services that ought to exist.

Finally the question forces itself forward as to how economical Congress itself is. It will be sufficient to cite a single case. Last year at the time when Mr. Roosevelt was in controversy with Congress over matters relating to the secret service, Mr. J. R. Garfield, then Secretary of the Interior, made certain statements supporting the Congressmen rather than the President. Observe the result, \$1,000,000 is promptly voted to the Secretary for the prosecution of land frauds in his Department. The previous appropriation had been \$400,000, and while the Secretary had asked for an increase it was entirely clear to everyone familiar with the situation that the large appropriation came quite as much as a reward of merit as because of the needs of the case. A good many Congressmen were angry last February, and, human nature being as it is, it is not surprising that personal feelings entered into some of the legislation of the closing days. Congress is not economical nor do many of the members work hard enough to have any real comprehension of the business side of the Government. A well informed and candid Congressman, in private life the director of large enterprises, estimated that the most hard-working men on the appropriations and other big committees put in about sixty days in the year on the real work of the Government as distinguished from politics and personal service to constituents. Those on other committees put in not more than five or ten days of similar work. If the Nation is to have a real business administration at Washington it is evident that these conditions must be changed, and it ought also to be clear that we who are away from Washington must give consideration to means as well as to ends if we are to effectively campaign for legislation requiring expenditure. It is a weak position to demand of Congress additional things, and then not to be prepared to support Congressmen in cutting off something else to grant the requests made. Nevertheless this country is rich enough to meet every legitimate expenditure, and provided the money be properly spent, the country will support as large appropriations as may be needed for public works and conservation.

Ely Central and Its Critics.

Our New York contemporary, *The Engineering & Mining Journal*, has recently severely criticised the methods used in promoting the Ely Central Copper Company. In this it has our entire sympathy. Readers of our own New York letters will remember constant warnings to the effect that the stock was being systematically boosted to an unwarranted height. This, in itself, would not be worthy of much comment since many better known and intrinsically valuable copper stocks, such for example, as Amalgamated and Nevada Consolidated, are now selling at prices out of all harmony with the security back of them, and the dividends paid, as compared, for example, with high-class bonds. The truth is that copper stocks, in particular, are selling now at inflated prices to people who buy with an eye rather than hoped-for future unloading prices than to ore reserves or earning capacity. Much of this is due to the gambling spirit of the ordinary buyer. Some is due to manipulation from the inside; as bad, even if more adroit, as that charged to the Ely Central. We seldom undertake to analyze the price at which mining stocks sell, for the reason, as stated, that the selling price under usual conditions bears no fixed relation to the value back of the stock. As to Ely Central, the property is clearly in an unproved stage, and the business organization is as certainly not one which warrants the public in buying the stock except as one might bet on a roulette wheel. All this is and has been clear from the first to any intelligent reader of the advertisements which have been scattered broadcast through the country. It will take, however, more than one such exposure to change the common buyer's attitude toward such stock. While we approve of the work done by *The Engineering & Mining Journal*, we may also suggest that there are more worlds to conquer and bigger boys to lick.

Incidentally the controversy has brought out some interesting points regarding the genesis of the Ely deposits which are worthy of careful study. In another column Mr. C. S. Herzig, who needs no introduction to our readers, presents some data regarding the Ely Central which put the matter of finding ore under the rhyolite in a much more hopeful light. If the secondary enrichment of the deposits took place before the rhyolite outflowed, there is no reason why the monzonite under the present capping may not be found to be valuable; which, it hardly seems necessary to add, is by no means saying that it will be so found. The question, too, of the possible value of deposits in the limestone cannot be summarily dismissed. Indeed, in accordance with observations elsewhere, the limestone would seem extremely likely to contain orebodies. We are glad to know that the United States Geological Survey has been investigating the Ely deposits. Mr. Arthur C. Spencer, the geologist in charge, is well qualified to pass on the subject, and his report will be awaited with much interest. Mr. A. C. Lawson's work in the camp in its early stages of re-juvenation was fundamental, but it is none the less possible that Mr. Spencer may find proper ground for difference of opinion in some particulars.

COPPER DEPOSITS OF SILVERBELL, ARIZONA.

Written for the MINING AND SCIENTIFIC PRESS
By C. F. TOLMAN, JR.

Silverbell is situated about 35 miles slightly north of west from Tucson, Arizona, and is connected with the Southern Pacific railroad by a branch at Red Rock. Formal work was started in 1902 by the Imperial Copper Co., although previous to this time a number of attempts had been made to work the mines, all of which ended in failure or only half success. The product of the mines is handled at the Sasco smelter, which is already an important copper producer, the monthly product averaging about 1,000,000 lb. of copper. Almost nothing has been written about the geology and ore deposits of this region, and as they present a number of novel points, and as the district promises to become an important copper centre, I will endeavor to present the salient features in a sketchy manner. Accurate maps and data could hardly be presented without the consent of all concerned, and therefore all figures are to be considered as diagrams, representing the structure only in a general way.

Geology.—The district presents fragments of the Paleozoic series, an alaskite porphyry intrusion, and many later andesite and trachyte porphyry dikes. The covering formations of no interest economically are rhyolite, andesite, tuff, detrital sand and conglomerate, and recent basaltic flows. The shattered limestone blocks, floated up on the alaskite porphyry, do not furnish the data necessary for compilation of the geological column. In the adjoining Silver Hill mountains 3700 ft. of alternating quartzites, shaly quartzites and limestones, and massive limestones, are exposed. These show Carboniferous fossils in the massive limestone, and no fossils have been found in the quartzites and shaly quartzites. There is no exposure here of the underlying Pinal schist which

rhyolite porphyry, belonging, therefore, to the family of rock known as alaskite. The igneous rock is in

Fig. 2. Sketch Showing Geology of Portion of Three Levels of the Mammoth Mine, Silverbell.

much greater bulk than the sedimentaries, and fills the space between them in an irregular manner. The rhyolite porphyry predominates, and kaolinizes

Fig. 1. Sketch of the Geology of the Vicinity of Silverbell.

is found in many of the fault-block mountains west of Tucson.

The Intrusion.—This is a very acid granite and readily, as it is very porous to the downward percolating waters. The coarser granite porphyry occurs in zones and lenses in the rhyolite porphyry,

and occasionally in distinctly later dikes. Detailed geological work may possibly show a genetic relation between this intrusion and the extensive rhyolite flows to the north. The sketch attached (Fig. 1) will give a graphic notion of the relation of the lime blocks to the intrusion. Very heavy contact zones develop along some of the contacts. Garnet, magnetite, specularite, quartz, epidote, copper-bearing pyrite, and chalcopyrite, are the most important of the minerals developed. At certain contacts, especially where the porphyry extends between the shattered blocks, quartzite develops, which in places is a very acid phase of the porphyry, and again may be a silicification of the limestone (Fig. 1).

The Orebodies.—Several types of orebodies occur:

and silver are found in the Silver Hill mountains. All this is in accord with the general law that the silver-lead deposits are formed farther from the intrusion than the copper ores.

The Imperial orebodies.—There are two types of contact orebodies worked by the Imperial company. The Mammoth orebodies are smaller irregular lenses of high-grade chalcopyrite ore, while the Union-Billy ore-zone furnished large copper-bearing pyrite orebodies of the more normal type. The former occur along a branch dike of the rhyolite-porphyry in the limestone. The sketch of a small portion of the first, second, and third levels, adapted from the mine maps, indicate something of the irregular shape of the ore-lenses, and the relation of these bodies to the main contact (Fig. 2). These sketches must not be

(1) Contact bodies in limestone. These have been worked in the old Atlas mine. They are producing most of the ore of the district in the Imperial holdings. They are evidenced by heavy garnet caps in the Oxide's properties, but have received scant attention here as yet. (2) Disseminations. These have undergone some preliminary prospecting by the Tiro and the Oxide companies, and more recently by the Imperial Copper Co. Local mining men are testing leached stained porphyries southeast of the Oxide Copper Co.'s properties. (3) Fissure veins in the porphyry. These are of scientific interest only. (4) Fissure veins at some distance from the porphyry. Veins in the rhyolite two miles north of Silverbell have furnished some rich lead-silver-gold ore. Strong fault-fissure veins containing copper, lead,

taken to indicate disappearance of the ore, for the fourth level has produced many times the ore of the upper levels, and general improvement in depth is marked. The numerous dikes, some of which are shown in the sketch, seem to bear no genetic relation to the ore, some of them being later than and cutting the orebodies. A well defined fissure follows the general trend of the contact, and goes by the name of the 'Mother Fault'. It does not show much movement, and is probably one of the later features of the deformation of the region. It has been thought to have some effect on the distribution of the ore, but this relation is far from demonstrated. It may be said that the chalcopyrite orebodies form outward from the rhyolite-porphyry on the hanging wall of the ore-zone, down into the lime. When the limits of

one orebody have been defined the procedure is to cut back to the porphyry and explore the contact until another lens or stringer is found leading into the lime, which of course is followed and developed. The lenses consist of chalcopyrite, pyrite, quartz, molybdenite, and occasionally wulfenite. The ore is undoubtedly original, no sign of secondary enrichment showing, and therefore making an interesting case of primary ore of commercial value. North of the Mammoth ore-zone, the Union and Billy shafts have developed large orebodies. The copper minerals are copper-bearing pyrite with some chalcocite and chalcopyrite. Associated, especially as caps above the ore-shoots, are the contact minerals. Some of the contact zones are so dense that almost no alteration is noticed even at the surface, and without any subsequent enrichment they carry sufficient copper to be mined as ore. Recently the Imperial Copper Co. has been pushing developments of the copper-bearing porphyry. Mr. Staunton, writing of the possibilities of these disseminated ores, states: "We think the probabilities very great in this way, especially north and east of Silverbell, and are beginning extensive prospecting of this ground by both drill and shaft, with results that are already encouraging."

At the Tiro development has been confined to opening a disseminated chalcocite orebody in the porphyry. Where first struck this orebody furnished remarkably high-grade ore, shipments containing 20% copper being reported. The ore is in a brecciated and leached porphyry, the copper occurring as disseminated specks in the rock, and also as veinlets, filling the fractures of the breccia-zone. In rock reported to assay as low as $1\frac{1}{2}\%$ the disseminated specks of chalcocite can scarcely be noted by the naked eye, while 4% ore shows both disseminations and veinlets. The upper portion of the orebody is now undergoing oxidation and downward migration, and here the oxidized products, cuprite and melanconite, are in evidence. The surface outcrop of this orebody is a brecciated silicified zone, showing copper silicate and carbonate stains.

Other disseminated deposits.—Throughout the southeastern portion of the belt, especially in the holdings of the Oxide Copper Co., locally better known as 'the Young America property', are extensive areas of iron-stained porphyry, stained also in places by salts of copper. The porphyry is alternately kaolinized and silicified. The ore mined by the early prospectors was from a brecciated zone, very silicious, containing native copper. This ore has been mined for converter-lining in a small way. In some of the tunnels of the Tiro company the disseminated chalcocite zone has been reached.

Veins in the porphyry.—A fine example of this group is found southeast of the Mammoth shaft. These are interesting on account of the minerals shown, which are quartz, fluorite, molybdenite, and chalcopyrite. These veins are of the same date as the general mineralization of the porphyry, a mineralization of course of no economic importance except as the products have been secondarily concentrated with disseminated deposits by descending surface-waters.

GRANITES.

Written for the MINING AND SCIENTIFIC PRESS
By GORDON SURE.

Granites were formerly considered by many to result from the burying and subsequent re-crystallization of sediments, but this view has been generally abandoned, owing to increasing knowledge, and granites are now regarded as generally true igneous rocks, which have been forced from below, while molten, into the outer crust of the earth. Some smaller bodies, being offshoots which were intruded between stratified rocks, are often found to rest upon rocks other than granite, but the thickness of the large granitic masses, such as form the cores of mountain ranges, is unknown. While erosion in some regions has carried away the granite to depths which can be expressed in miles, no bottom to the larger masses has been revealed. Were granite of sedimentary origin, surely some trace of the original floor would be discovered at times. The great thickness of the granite masses, with their uniformity in composition, is alone sufficient to point to an igneous derivation, to say nothing of the evidence furnished by other facts observed in the field, and by the differing chemical analyses of granites and sedimentary rocks.

Granitic rocks are deep-seated, and are only naturally exposed through the removal of the beds which once overlaid them. It is reasonable to suppose, both that many granite areas have not yet seen the light of day, and that others once exposed are now buried beneath sediments. In the light of these probabilities and the known abundance and unknown thickness of granitic rocks, it is clear that their volume must not only be immense, but, like the famous caverns in Xanadu, 'measureless to man'. Volcanic rocks cover thousands of square miles of the earth's surface, but, their thickness being limited, their total amount is probably small compared to that of granitic rocks.

Granite gets its name from the Latin *granum*, meaning a grain, on account of its granular texture, and mainly consists of alkali feldspar, quartz, and small amounts of either mica, hornblende, augite, or other minerals, one or more of which may be present. Generally the feldspar is chiefly a potash variety, either orthoclase or microcline, but, in some granites, the principal feldspar may be albite, which is a soda feldspar, or anorthoclase, a potash and soda variety. Granites, however, are usually classified according to the relative abundance of the minor constituents, giving rise to such terms as muscovite-granite, biotite-granite, hornblende-granite, augite-granite, tourmaline-granite, and others. The chief minerals in ordinary granite are feldspar, quartz, and mica, the first being mainly potash feldspar. Most granites contain not only alkali feldspars, but also small amounts of soda-lime feldspars, which latter may often be distinguished by the fine parallel lines upon them, seen with or without a lens. When these two kinds of feldspar are present in approximately equal quantities, the rock is known as quartz-monzonite. When the soda-lime feldspars are greatly in excess, or the alkali varieties are absent, or nearly

so, the rock becomes quartz-diorite, hence, quartz-monzonite stands between granite and quartz-diorite. Little true progress can be made in the study of rocks until it is realized that they grade into one another, hard and fast lines between them being purely imaginary.

Syenite may be defined as a granite containing little or no quartz, and with increasing amounts of soda-lime feldspars it passes through monzonite into diorite; it is a rare rock, the 'syenite' of the miner being generally something else. The name is from the ancient Syene, in Egypt, now called Assuan, and here the Egyptians opened great quarries from which came the obelisks in New York and London. The Assuan rock, however, is a granite containing mica, and also hornblende in portions of it, and it is noteworthy that these obelisks have sustained more injury from exposure for a few years to the climates of New York and London than they suffered during over three thousand years in Egypt. Gneiss, unless qualified by some prefix, has the same constituents as

and may be absent in both aplites and pegmatites. Quarrymen and stone workers term various rocks granite, 'black granite', for example, including gabbro, diabase, and diorite.

As is well known, the color of granite varies, and although the other minerals have some influence, the general color of the rock almost invariably depends upon that of the feldspars. A red or pink color is thought to be due to the presence of extremely small particles of hematite in the feldspars, while minute crystals of epidote and scales of chlorite give rise to greenish tints. When red or pink feldspar, and that of another color are observed in the same granite, the former is almost certain to be a potash variety.

Rhyolite is the volcanic equivalent of granite, and in like manner latite bears the same relation to monzonite, trachyte to syenite, phonolite to nepheline-syenite, dacite to quartz-diorite, and andesite to diorite. That granite was formed under pressure is indicated by the presence of liquid carbonic acid in some of the small cavities in the quartz of granites,

for this gas can only be liquefied by pressure, and it is further evidenced by the granite minerals themselves, which seem to have crystallized out, not from a simple dry fusion, but from material containing superheated water and often other substances, some of which, being volatile under the conditions, would have more or less escaped had they not been confined. The relations to each other of the minerals in rocks show the sequence in which they must have formed, and in granites the mica and hornblende have generally crystallized first, then the feldspar, and lastly the quartz, and yet quartz is far more infusible than feldspar; the successive crystallizations, be it, said, are likely

Weathered Granite Surface. Showing Boulder Forms.

ordinary granite, but they are arranged roughly in bands, although, unlike a schist, the rock does not split readily. The names 'granulite' and 'binary granite' have been applied to granites containing little or no mica, hornblende, etc., but the former having been employed in a restricted sense, and the latter being awkward, J. E. Spurr has proposed the term 'alaskite' for granular quartz-feldspar rocks of this kind, a name, be it said, which seems as good as any other. Pegmatite is a coarse-grained granite, occurring as dikes, veins, and irregular masses, being usually more silicious than ordinary granite, sometimes in fact grading into quartz veins. The principal minerals, while the same as in granites, vary in their proportions. Pegmatites seem often to have been formed during the last stages of the cooling of granite masses, when water and silica were abundant in the material from which they crystallized, and it is interesting to note that many elements present in granites only in very small amounts are sometimes concentrated in pegmatites. In the variety of pegmatite called 'graphic granite', the quartz and feldspar evidently crystallized at about the same time. Aplitite is a fine-grained granite, much finer in grain than ordinary granite, and like pegmatite is generally higher in silica than granite, and usually occurs as dikes and veins. Mica is deficient in aplites

to overlap, thus causing the growing minerals to interfere with one another to some extent. Again, quartz and alkali feldspars have never been artificially made by the cooling of dry melts in spite of numerous attempts, but they have been so prepared in the presence of water under pressure. The white mica, muscovite, has not as yet been found as a primary mineral, save in deep-seated rocks, especially granites, and as it contains water and when heated fuses to a glass, it manifestly did not crystallize from a dry fusion. Muscovite also contains fluorine, the best developed specimens being seemingly those richest in this element, and it is interesting to note that in making any mineral artificially, compounds of fluorine, boron, and other elements, frequently present in granites, greatly facilitate crystallization, although water is probably of the greatest importance.

Without going into more details it seems that granitic rocks result from the slow cooling and crystallization of heated material under pressure, containing water and often other bodies which promote crystallization, and that solidification takes place at a temperature no higher than a dull red heat, for granites contain minerals which lose some of their physical properties above that temperature. Thus, strange as it may appear, the crystallization evidently occurs at a temperature considerably be-

low the fusing points of most of the granite minerals, the material undoubtedly remaining liquid chiefly on account of the presence of water. Aplite is often found in minute cracks and openings in rocks, indicating not only that the matter must once have been very liquid, or possibly even gaseous, but that pressure was required to force it into these small spaces, and estimates have been made of both temperature and pressure by measuring the amount of contraction of the fluids sometimes seen partly occupying small cavities in the quartz of granites. Obviously, when the molten matter which subsequently cools as granite is forced into overlying rocks the latter must be of sufficient thickness to prevent rapid cooling, and must be strong enough to resist the pressure from below, otherwise the liquid material would be poured out on the surface. It therefore follows that granites and all deep-seated rocks have solidified, not only under the pressure from below, but also under that exerted by the weight of the overlying rocks, and consequently granites are naturally exposed only through the removal by erosion of the formations which once overlaid them.

When the pressures and strains accompanying intrusions of igneous rocks are considered, it is small wonder that in some localities granite is still under a compressive strain, which is shown not only by vertical drill-holes becoming partly closed and by the crushing of cores between adjacent holes, but also by the sudden formation of fissures in quarries. T. Nelson Dale states that, owing to the strain, a sheet of granite was actually extended 5 ft. in a quarry at Concord, New Hampshire,* and in some quarries the granite, when split in large sheets, breaks with an explosive sound; the openings made in quarrying, of course, give rocks under strain opportunities to adjust themselves. The granites of some of the Eastern States are ably described by Mr. Dale in Bulletins 313 and 354 of the United States Geological Survey.

Granite seems almost always to be divided into sheets, by fractures which are roughly parallel to the present surface, these sheets increasing in thickness with depth, and it is probable that this structure is mainly owing to compressive strains, although the thin sheets at and near the surface may have been partly formed through expansion caused by the heat of the sun. The relief of pressure due to the removal, by erosion, of the rocks originally overlying the granite would naturally assist in the formation of sheets. Joints, more or less at right angles to the fractures causing sheets, are also common, and in many cases the rounded forms resembling boulders, which granite often assumes in weathering, are primarily due to these various cracks. Evidently if a mass of rock be already to some extent divided into blocks by fractures, the corners of these blocks will be the first to suffer in weathering, and I have seen granite hills literally strewn with masses, large and small, looking just like water-worn boulders, and yet all were practically in place. In many of these rounded forms the agencies of weathering, such as changes of temperature and freezing of absorbed water, have developed concentric cracks giv-

ing them the structure of onions, so that thin shelly pieces scale off. Other causes besides weathering and relative scarcity of joints are likely responsible for great granitic domes, such as those grand examples in the Yosemite region, California, and possibly arches in the rocks which originally overlaid the granite, determine both the location and shape of the domes to a large extent. Folds would naturally be produced by or at the time of the intrusion of the granite, and in some cases, even should they have been lacking, the granite may have worked its way upward in spots by a kind of 'stoping' method, due to blocks from the roof becoming loosened and finally sinking in the molten mass.

Many rocks, especially in arid regions, outwardly present a dark, smooth, shiny appearance due to what is aptly termed 'desert varnish', but granites, particularly when coarse in grain, seemingly often weather too rapidly for this coating to form, so that they more or less retain their natural color. Hence, what with their characteristic rounded and boulder-like shapes and the frequent absence of the dark desert varnish, granitic rocks in desert countries are often easy to identify, though far away, and the accuracy of the determination can frequently be confirmed by carefully noting the character of the wash brought down from distant ranges. Desert varnish seems to have been produced by water, which, after soaking into the rocks, has subsequently been brought to the surface and evaporated by the heat of the sun, depositing the substances dissolved in a relatively insoluble form, the hard thin coating often consisting of quartz, iron oxide, and some manganese oxide. Thus, although an effect of weathering, this case-hardening greatly protects rocks from destruction, and is an excellent illustration of one method of adaptation to environment and the survival of the fittest in the inorganic world. The smooth shiny exterior may be due in part to the action of sand blown by winds, the sand-blasts polishing the varnished surface, but cutting deeply into rocks not so protected. Suffice it to say in this connection that while volcanic rocks, quartzites, and schists may take sharp angular forms, granitic rocks tend to become rounded, and, though in place, to assume the appearance of boulders.

Among minerals which are usually associated with or derived from granitic rocks may be mentioned the ores of tin, tungsten, molybdenum, tantalum, the metals of the rare earths, and various gems, some of these minerals being generally present in granites only in very small amounts, but sufficiently concentrated in pegmatites to be of economic value. Prospectors in search of gold and the more common metals are often unreasonably prejudiced against granitic rocks, and yet not only are there numerous excellent mines in granite, but many ore deposits though in other formations are directly due to the intrusion of granites, monzonites, and allied rocks in their vicinity. Fissures are naturally formed by the movements attending intrusions, and in a number of cases ores have undoubtedly been deposited from solutions derived from granitic rocks. Many a prospect can never be developed into a paying mine simply because it is too far from the granite.

*Bulletin 313, U. S. Geol. Surv., p. 36.

OLIVER CONTINUOUS FILTER.

Written for the MINING AND SCIENTIFIC PRESS
By A. H. MARTIN.

The Oliver continuous filter is the invention of Edwin Letts Oliver, metallurgical engineer for the North Star Mines Co., at Grass Valley, California. The filter consists of a rectangular wood or steel tank in which is partly submerged a filter cylinder revolving once every five or six minutes. The tank contains the slime, which is kept at a constant level by an automatic float. The filter-drum, through which passes a hollow trunnion, is composed of wooden staves mounted on cast-iron spiders. The surface of the cylinder is divided into 24 compartments, each section attached to an automatic valve by both a blow-pipe and vacuum-pipe, for the connection of suction and of compressed air respectively. The outer periphery of the compartments is covered with a specially prepared filter medium, in turn covered with light canvas. The entire drum is

Oliver Slime Filter.

wrapped with hard steel wire. Against the side of the cylinder, resting on the wires, is a flexible steel scraper, designed to assist the removal of the slime-cake.

The first filters built two years ago were 7 ft. long and 10 ft. diam., and have an approximate hourly capacity of two tons. All other filters operating in Mexico and this country are 11 ft. 6 in. diam., and of lengths varying from 7 to 14 feet.

When the formation of the cake is commenced a vacuum is applied to the vacuum-pipe by means of the automatic valve. The suction is equivalent to about 22 to 25 in. of mercury. The suction causes a cake of slime, from 1/4 to 1/2 in. thick to adhere to the submerged section of the cylinder. As the cake emerges from the slime it is dried to a consistence of about 30% moisture. A wash is then applied, which removes the last traces of dissolved gold and silver, and compressed air at 5-lb. pressure is admitted through the pipe to the section opposite the scraper. The vacuum is temporarily shut off at this section automatically, and the air admitted, which causes the cake to detach from that section and slide

down the scraper, from which it is removed by a spray of water, or by a belt-conveyor in case abundant water is unavailable. The change from suction to pressure takes place in one compartment immediately before reaching the scraper, and, after passing, the suction is at once restored. All of this is accomplished automatically. The cleaned canvas again passes into the slime and is ready for another cycle. It is thus seen that the action of the filter is continuous.

The weight of pulp on one side of the filter nearly balances the weight on the other, and but little power is required for operation, 10 hp. being ample for a 100-ton plant, including power for filters, vacuum-pump, and compressor.

Four of these filters have been in use at the North Star mines for two years, two at the North Star cyanide plant, and two at the Central cyanide plant. They have a capacity of 40 to 50 tons each, and have been treating a sticky clay slime, free from sand, and they have given excellent satisfaction. Practically a total recovery of the dissolved metals is accomplished, the residue showing less than 5c. per ton dissolved gold, even with the treatment of high-grade slime, which frequently occurs at these mines. Freedom from shut-downs, and small costs of labor and repairs, have tended to make these filters popular.

In addition to the filters in use by the North Star Mines Co., 20 are used in Mexican mills, and American plants. Both gold and silver ores are being treated, and results have been satisfactory in every instance, high-grade ores being as thoroughly washed as low-grade. The principle involved is a new one, and the filters are attracting the attention of metallurgists whenever they have been introduced in a new district.

Below is given a summary of costs of treating slime at the central cyanide plant of the North Star Mines Co. The mill-tailing is classified into sand and slime, and concentrate from the tables is also treated, so that one-third of the labor at the plant is charged to each product treated. As the tonnage is relatively small, the labor-cost bears a large proportion to the total cost of treatment.

INDUSTRIAL ACCIDENTS AND EMPLOYERS LIABILITY LAWS.

By DAVID ROSS.

*While the great loss of human life, consequent upon the operation of modern industry makes constant and proper appeal to the sympathetic, our treatment of the legitimate claims of injured workmen should be uninfluenced and as free as possible from considerations inspired by sentiment alone. From our present knowledge we are permitted to form a fairly correct estimate of the extent of the losses and suffering which the growing business and industrial interests of the country impose.

These, in the extra hazardous occupations, increase and decline in nearly exact proportion to the number of men employed and the amount of work they perform. There is but one effective way to prevent accidents, that is, to stop working. F. L. Hoffman, of New York, in the September, 1908, bulletin of the Bureau of Labor, estimated that the total number of fatal accidents in the United States last year was between 30,000 and 35,000. Out of an industrial population of nearly 30,000,000 the death toll last year was approximately 18,000. Our triple interests, transportation, mining, and manufacturing, represent in the order named the most hazardous occupations and make up the principal list of fatalities. Under the provisions of the British Workmens' Compensation Act, which requires in the case of death from accident a consideration equal to the total of three years' average earnings, our financial liability for the year 1907 would have totaled less than \$22,000,000.

Aside from railway statistics concerning accidents, we have nothing authentic as applying to the entire country. In the State of Illinois, the Mine Inspection Service, through the Bureau of Labor, has been collecting and publishing accident and other statistics for the past 30 years. Taking the per cent of accidents, of which we have a record in mining, manufacturing, and transportation in Illinois and applying them to those industries for the whole United States, gives the following approximate results:

| Industry. | No. Employed | Total Annual Wages | Value of Product. | Average Yearly Earnings |
|----------------|--------------|--------------------|-------------------|-------------------------|
| Coal mining... | 586,801 | \$368,832,322 | \$614,798,898 | \$629 |
| Manufacturing | 4,244,538 | 2,266,273,319 | 14,802,147,087 | 534 |
| Transportation | 1,403,840 | 882,726,920 | 2,589,105,578 | 629 |
| Totals | 6,235,179 | \$3,517,832,561 | \$18,006,051,563 | \$564 |

| | No. Killed. | No. Injured. |
|----------------|-------------|--------------|
| Coal mining | 2746 | 10,600 |
| Manufacturing | 900 | 8,400 |
| Transportation | 4534 | 87,644 |
| Totals | 8180 | 106,644 |

The following indicates, approximately, what part of the wealth produced through these agencies would

*Abstract of address before the American Mining Congress, Goldfield, Nevada.

be required to pay an average of three years' wages to the heirs of dependents of those killed, and compensation at the rate of one-half wages to those injured losing an average of 60 days' time each:

| | Per cent to pay for killed | Per cent to pay for injured | Per cent to pay for killed and injured |
|----------------|----------------------------|-----------------------------|--|
| Coal mining | 0.89 | 0.09 | 0.98 |
| Manufacturing | 0.012 | 0.003 | 0.015 |
| Transportation | 0.35 | 0.18 | 0.53 |
| Totals | 0.09 | 0.03 | 0.12 |

The addition of less than 1% to the valuation of the coal product of the country would furnish sufficient revenue, including the cost of administration, to cover the claims of the killed and injured according to the terms of the British compensation law, while twelve hundredths of 1% would perform a like service in the case of all casualties occurring in connection with mining, manufacturing, and transportation in the United States.

Legislation relating to the liability of employers contemplates the recovery of damages for injuries resulting from negligence. Under our system of judicial procedure, the burden of proving negligence rests upon the plaintiff, and the chief difficulty has been to produce the evidence. There are many accidents of such a nature that it is impossible to show responsibility on either side. Recovery is out of the question. There has also grown a system of judicial law, based on the relationship of the plaintiff to other workmen, known as the rule of fellow-servant or co-employment, the rule of contributory negligence, the doctrine of assumption of risk, and other vague and mysterious legal speculations that operate to defeat just and meritorious claims. Employers, on the other hand, complain, and with some justice, that legislatures, influenced by the love or fear of trade unions, are continually enacting laws against their interests; that the judgment of juries, softened by tears of tender-hearted attorneys, return verdicts in total disregard of justice conditioned more upon the amount the defendant can afford to pay than the loss sustained by the injured person; that unscrupulous lawyers take advantage of the situation and for a fee contingent on the verdict, encourage the prosecution of such claims; and that as a means of preserving their credit and avoiding bankruptcy, they are compelled to pay large premiums to casualty companies for incomplete protection. Out of this situation has grown the business of indemnity insurance. C. R. Henderson, of the Chicago University, in his recent work on 'Industrial Insurance', states that in one year 15 companies in Illinois collected in premiums \$1,825,467.57, and paid claims to the amount of \$867,940.95. He explains that it must not be inferred from these figures that this class of insurance companies is earning inordinate profits. It is claimed that the rate of commission alone for securing business, averages 25 or 30%, that the addition of other items such as salaries and expenses of special agents, rents, clerk hire, surveys, and inspections, would average one-half the premiums, leaving

the margin of profit about 10% of the receipts.

So far as insurance companies are concerned the extent of their profits whether large or small, is immaterial, the facts are that the system fails to meet the requirements of the occasion; that it is maintained at enormous cost to the industry without adequate benefits to the interests directly involved. It would seem that an institution which on the one hand fails to give complete protection to the employer, and on the other hand applies the greater part of its premium in an effort to defeat the claims of employees, is without defense. Beyond the premiums paid to registered insurance companies we have no means of knowing what such insurance costs. It is impossible to institute anything like a correct comparison, without an actual trial, of the expense of continuing present plans with that of compensating accidents according to a definite schedule. Whether the sum were less or more, there would, under the proposed system, be the satisfaction that whatever was disbursed would be distributed in a way that would render the greatest and promptest relief to the unfortunate victims of industry.

It might be asked if the adoption here of a measure similar to the workmen's compensation act of Great Britain would end all litigation so far as accidents are concerned. It would not, for the reason that the right to bring action in court to recover damages cannot be abridged, but here, as in other countries, the usual tendency would be to accept without litigation a specific sum rather than take chances on the uncertain results of a law suit. It would be better for everyone if this reform could be brought about through the medium of trade agreements, but, on account of the limited number who are affiliated with labor unions and organizations of employers, this is impossible and we must look to the compelling influence of general law to accomplish it.

INSURANCE AND MINE ACCIDENTS.

By G. W. TRAER.

*The consideration of insurance in connection with mine accidents usually relates to employers liability insurance only. While there may be some such cases, personally I know of none where a mine operator provides ordinary accident insurance for mine employees. In any event, mere accident insurance would not protect the mine operator against employers liability, until the actual acceptance of the insurance money by the person having the cause of action, in extinguishment thereof. A general practice of mine employees carrying collective accident insurance for themselves, in adequate amounts, would be highly commendable, because it would relieve a vast amount of misery and the distressing effects of abject poverty as well as beget or increase a tendency to thrift. But that question should be settled voluntarily by the employees themselves. Requiring an employer to furnish accident insurance for his employees would be merely an indirect form of compulsory compensation from employer to employee for all personal injuries. Employers may well consider

carefully whether some direct form of workmen's compensation for all injuries not caused by workmen's own misconduct, would not be highly preferable to the present wasteful and otherwise objectionable methods of litigation relating to compensation for personal injuries. It is believed by those in position to know something of the facts, that claimants on the average receive much less than half the total amount paid out by employers on account of personal injuries, court costs, and lawyers' fees, and expenses absorbing much more than half of the total amount expended. Such condition requires the most careful consideration upon the part of men of affairs.

The doctrine of employers liability for certain injuries sustained by work people in their employ is so deeply imbedded in American law, that it seems impossible to doubt that, in one form or another it will remain so. In its origin and down to comparatively recent years this liability depended upon distinct negligence on the part of the employer and it was subject to several important qualifications. The employee was held to a large measure of responsibility for occupational accidents to himself, almost or quite equally so with the employer. The doctrine of employers liability had no foundation in merely sympathetic feeling or in the relative financial ability of employer and employee. To be entitled to compensation, the injured person not only must show that the employer clearly was negligent but that he himself was free from negligence. The courts controlled or influenced, to a large extent, the finding of verdicts by juries. But in recent years legislatures, courts, and juries, have greatly broadened the scope of the employer's liability, and correspondingly lessened the responsibility of the employee for himself. At the present time an employer's neglect to comply with a statutory requirement practically makes him an absolute insurer of his employee's safety, in matters covered by the statute. Contributory negligence on the part of the employee cannot be pleaded. To recover a verdict it is necessary to show only that the person was injured and that neglect to comply with a statute was the proximate cause; and the word 'proximate' is given a liberal interpretation in favor of the plaintiff. In comparatively few cases do courts interfere with findings by juries, even though bias is plainly apparent.

The trend of public feeling, though not yet fully crystallized into definite public opinion and action, clearly seems to be in the direction of recompense to work people for substantially all occupational injuries. Care by employers for employees' lives and safety has greatly increased both voluntarily, by reason of higher moral sense on the part of employers, and by force of laws. In spite of this fact, employers' expenditures on account of personal injuries to employees has greatly increased during recent years. Litigation has been multiplied and the methods by which much of it is originated and carried on are degrading and subversive of respect for law.

Employers' liability insurance has had a large growth during recent years, but being merely a commercial venture for profit, it has accomplished

*Abstract of paper read before the American Mining Congress, Goldfield, Nevada.

nothing in an ethical sense. The matter is less properly a subject of commercial venture than life, fire, tornado, ordinary accident, or fidelity insurance. In those branches of insurance the mere occurrence of a certain event fixes liability upon the insurance company; it usually fixes the amount to be paid also, and there is comparatively little inducement to speculate on the outcome of litigation. Except in fire insurance, practically nothing can be done in the branches of insurance mentioned to avoid the occurrence of the event insured against. Mutual insurance limited to employers in the same light only, is better applicable to employers' liability for several reasons. Experienced men working almost directly in common can accomplish more in the way of preventing injuries. Their practical knowledge and experience is more directly available in the investigation of accidents and assisting to untangle technical facts and rules of law. Their local knowledge of persons and circumstances, frequently of great value, is drawn upon more freely; and altogether they are likely to feel and to exert a more direct interest in the details of mutual liability insurance than in the case of commercial liability insurance. As a matter of fact, mutual employers' liability insurance is no more than a co-operative method of seeking to lessen the frequency of accidents and of investigating and adjusting claims and averaging the ultimate cost. But the great problem which is nearing an acute stage is not a question of one form of insurance or another. There is a rapidly growing belief that society as a whole should bear the burden of industrial injuries, and the great industrial and humane problem to be worked out is how to distribute the burden equitably. This problem cannot be ignored. Willingly or unwillingly, employers must accept the solution finally reached, and it will be wisdom on their part to share in bringing it about.

A NUGGET WHICH MAY HAVE GROWN.

Whether gold nuggets grow or not in placers is a disputed question. The evidence in favor of such a hypothesis has never seemed conclusive, but each contribution tending to establish such action is of interest. There seems to be no reason why solution

Fig. 1. Magnified 3 1-2 Diameters.

and re-deposition of gold should not occur in placers under certain conditions. In recent gravels the usual absence of sulphides would of course preclude the formation of the *ic* salts of iron and copper, which seem to be mainly responsible for solution of gold in veins in the process of alteration. The compounds

in placers are necessarily almost wholly oxidized, and the effect of organic compounds could not be great in the presence of such abundant oxygen. In buried ancient placers, like those of the California gold-belt and of the Australian deep-leads, conditions are different, and organic sulphur has resulted in the formation of sulphides of iron to no small extent. But the evidence of chemical re-arrange-

Fig. 2. Magnified 3 1-2 Diameters.

ment of the gold content of these placers is singularly wanting. A recent discovery of a nugget in British Columbia raises anew the question of such probable solution and re-precipitation of gold in a placer. The nugget is shown in the accompanying illustration, magnified so as to bring out the detail. The magnification is direct, and is not obtained by enlargement of photographs. These views were made by O. H. Packer. The nugget was found by three brothers, F. D., E. W., and C. L. Condit, of Hazelton, British Columbia, and was washed out of an exceedingly argillaceous gravel, hard and com-

Fig. 3. Magnified 10 Diameters.

pact, from a depth of 20 ft. below the surface. This clayey gravel had been overlaid by a great depth of ancient glacial boulder clay, which had subsequently been eroded. The clayey gravel in which the nugget was found therefore has considerable antiquity. The deposit is about 120 miles east of Hazelton on Tom's creek, which flows into the Omineca river,

which in turn is a tributary of the Peace. The nugget is 1 in. long by 0.57 in. wide. As shown in Fig. 1 and 2, it consists of a mass of gold granules cemented by gold into a solid mass. The details, as revealed by the photographs, are as follows.

Fig. 1, obverse; nugget of wire gold and small gold grains firmly cemented. A few grains of quartz are imbedded between the grains of gold. Two of these quartz grains show crystallization faces and edges, though in each case the greater part of the original crystalline form has been obliterated by erosion. Many cavities occur in the gold grains, and the grains are cemented with gold. The cavities between the grains of gold extend entirely through the nugget in a few cases. The figure is magnified $3\frac{1}{2}$ diameters.

In Fig. 2 is shown the reverse of Fig. 1. On the

Fig. 4. (Above.) Magnified 30 Diameters.
Fig. 5. (Below) Magnified 28 Diameters.

lower right-hand projecting part a triangle face (octahedral crystallization) is plainly visible. Octahedral crystallization of gold is seen on several other small gold grains. The magnification is $3\frac{1}{2}$ diameters.

Fig. 3 represents a limited area of the nugget magnified 10 diameters. Cavities in the small gold grains show distinctly. Cementation is faintly shown.

Fig. 4 is of a limited area showing (a) gold cementation between smaller nuggets. In the centre of the field is seen a (d) gold grain showing distorted octahedral crystallization.

Fig. 5, a limited area magnified 28 diameters, shows (a) cementation with gold between the grains of gold, and (b) a cavity in a grain of gold.

YAKUTAT BAY REGION.

Yakutat bay lies at the base of the St. Elias range, about 30 miles southeast of Mount St. Elias, where the international boundary strikes due north. It is the only harbor on the 300-mile stretch of comparatively straight coast line between Cross sound, opposite Juneau, and Controller bay. The area has recently been discussed in detail by R. S. Tarr and Bert S. Butler, in Professional Paper No. 64, of the United States Geological Survey. According to these authors, the Fairweather and St. Elias mountains rise abruptly to great altitudes along the coast. At their foot, bordering the sea, is a lowland fringe or foreland of glacial débris. Numerous glaciers descend to the Yakutat bay foreland, the largest glacier on the American mainland, the Malaspina, a broad ice plateau covering an area as large as that of Rhode Island lying northwest of the bay. Hubbard glacier, at the northernmost point of the bay, is one of the finest examples of a tidal glacier on the continent. The Yakutat bay inlet has roughly the shape of a bent arm, with the shoulder at the ocean and the elbow at the foot of Hubbard glacier. The outer portion is called Yakutat bay, the mountain-walled stretch just south of the elbow Disenchantment bay, and the forearm portion Russel Fiord. Among the high peaks visible from the bay are Mounts Hubbard (16,400 ft.), Vancouver (15,617 ft.), and Cook (14,700 feet).

This region has been the scene of many explorations, an outline of which is given in the report. The first recorded visit was in 1786, when La Pérouse sent an officer into the bay in search of an anchorage. In 1792 Malaspina, an Italian in the service of Spain, was sent with two ships to test the accuracy of a report that the west end of the long-sought Northwest passage lay near Yakutat bay. The Russians built a fort at Yakutat in 1795. The more important explorations in the nineteenth century were those of I. C. Russell, of the United States Geological Survey, in 1890 and 1891, the international boundary survey in 1895, and the Harriman expedition in 1899. The expeditions on which the present report is based, were made in 1905 and 1906.

The Yakutat region is pre-eminently one of glacial phenomena, the topography being characterized as 'ice drowned'. The description of the origin, effects, present and former positions, and probable future history of the glaciers forms the major part of the report. Mr. Tarr states that the present glaciers are mere remnants of former ice floods which extended to the very mouth of Yakutat bay. Many of them are still actively moving and some descend to the shore. The topography of the region has been profoundly modified by the action of these glaciers in two ways—by erosion and by deposition. Deposition has produced the foreland fringe and minor accumulations of débris throughout the area. Erosion has broadened and deepened the fiords, truncated the tributary valleys, and left them hanging above the main valleys, steepened and straightened the valley walls, lowered divides, and, by irregular action, left nunatak knobs standing above the otherwise smooth fiord troughs.

FLUORSPAR GRADES AND MARKETS.

Written for the MINING AND SCIENTIFIC PRESS
By F. JULIUS FOHS.

*Fluorspar is classed as lump, gravel, and ground. Lump and gravel, spoken of together as crude fluorspar, may be had in three grades according to quality. Ground is to be had in four grades, but these are not correlative with the grades of crude fluorspar. The term 'gravel' is now used to include both the gravel resulting from disintegration of lump through natural causes, and a crushed product. Gravel is sold washed or unwashed. No. 1 fluorspar is usually white, less often slightly colored, and should run 96% or more calcium fluoride, the remainder consisting of silica, iron oxides, alumina, calcium and magnisiums, carbonates, alkalies, hydrocarbons, and moisture. Dark colored fluorspar, especially if somewhat shattered and iron stained, is not classed as No. 1, owing to the larger amount of silica it contains, such silica being deposited between the cracks in the weathering process. Colored fluorspar not so affected, if clear and highly crystallized, is not objectionable in this grade. Dark brown and purple black are not included in this grade at all, since they are usually charged with heavier and a larger amount of hydro-carbons.

American ground fluorspar is all No. 1 grade, but is classified into three sub-grades, Extra No. 1, No. 1, and No. 2. A still lower grade of ground is obtainable in England. No. 1 ground contains 98% or over calcium fluoride, and about 1% silica. This grade is generally used ground. Extra No. 1 contains less than 1% total impurities, with very little silica, and brings several dollars more per ton than No. 1. Extra No. 1 is produced from hand selected white lump fluorspar. While the bulk of that purchased by acid manufacturers is No. 1 (owing to the lower price), nearly all of Extra No. 1 also goes to them. No. 2 ground contains from 96 to 97% calcium fluoride with as much as 2% silica. It is of darker color than No. 1, the off color being due to the darker colored fluorspar, as well as to a small amount of lead, an impurity pleasing to some glass-makers. This grade is employed for cheaper wares of both the glass and enamel manufacturers. The bulk of the demand for ground fluorspar is for No. 1. Ground fluorspar is used, also, where a specially pure flux is needed. American ground averages 85 mesh in fineness. No. 2 fluorspar contains 90% or over calcium fluoride with less than 4% silica, the remaining impurities consist largely of calcite and sometimes limestone. Colored fluorspar, excepting unwashed and gravel, nearly all falls into this grade. The crushed product of the mills is also No. 2. Some of the lump of this grade will analyze 95% calcium fluoride, when it may be classed as Extra No. 2. This grade is largely used for fluxing purposes. No. 3 fluorspar includes, according to present usage, all material containing between 60 and 90% calcium fluoride. Unwashed gravel belongs to this grade, as does fluorspar associated with a considerable amount of calcite, limestone, quartzite, barite, and other

minerals. Mill tailing is No. 3. This grade is used as a flux in iron smelting, and especially where low-priced fluxes are necessary. A grade of English ground may be classed as No. 3 ground. This corresponds in quality with the best of No. 3 fluorspar, containing, it is reported, about 88% calcium fluoride.

I suggest that the fluorspar classed now as No. 3 be divided into two grades, to be designated No. 3 and No. 4; No. 3 to include fluorspar running from 80 to 90%. This grade would embrace most unwashed and not too dirty gravel; also lump fluorspar associated with not exceeding 12% silica in the form of quartzite, sand, or chert, and from 8 to 15% calcite or limestone. No. 4 would include all fluorspar containing 60 to 90% calcium fluoride, its silica content not to exceed 15%, with the remainder made up largely of limestone and calcite. This grade would embrace the mill tailing and fluorspar largely associated with quartzite or limestone. No. 4 grade would also embrace the artificial fluorspar by-product of cryolite. For the proposed No. 4 grade the demand is limited.

The ruling prices for fluorspar have remained practically constant for several years past. Occasionally a company has offered fluorspar at a lower price and caused temporary flurries in the market, but this only affected some particular grade and left no permanent effect. The difference in price between American grades No. 1, 2, and 3 crude, and also between the different grades of ground, vary from 50c. to \$3 per ton. Fluorspar of similar grade costs from 50c. to \$1.50 more in lump than in gravel, partly because of the higher cost of producing lump, and partly owing to the less silica content. Lump can be graded closer than gravel. Mining companies that do not market their own product sell the same to marketing companies at prices just sufficiently less than the ruling prices to pay the marketing companies for handling such product.

The imposition of a \$3 tariff on fluorspar has resulted in broadening the market for American fluorspar, without permitting an increase in prices. The latter are still regulated by foreign importations, but at Atlantic Coast ports and not at Pittsburg, as was formerly the case. The present cost of English fluorspar, including tariff at Baltimore, is \$6.10 per short ton, as against a minimum sale price of \$8 for domestic unwashed fluxing gravel, leaving a good margin in favor of the English. At Pittsburg, however, the conditions are now reversed; the present minimum cost of English fluorspar at Pittsburg would be \$7.44, whereas domestic unwashed gravel can be sold there for about \$7. This gives American producers the advantage of trade at practically all the open-hearth steel furnaces, since few, if any, are situated at coast ports or sufficiently near them to take advantage of English importations. The effect of English fluorspar competition will be felt at Pittsburg and vicinity until the large stock imported prior to the imposition of the tariff is exhausted. Nevertheless, large orders for domestic have already been given from that vicinity.

The range in prices f. o. b. mines, Kentucky-Illinois district, for 1908 were: unwashed gravel sold at \$4

*Published by permission of Charles J. Norwood, Director Kentucky Geological Survey.

to \$4.50; washed gravel (though a small amount of high-grade brought \$8) sold at \$4.50 to \$5.50; the average for all grades of gravel was \$4.62. No lump of No. 1 grade was sold. No. 2 lump brought \$5 to \$7, the average price being \$5.40. Although the average for ground was \$10.27, it sold in bulk as low as \$9; barreled ground for \$10.50 to \$15. The range in prices for 1909 has been: unwashed gravel, \$4.50 to \$5; washed gravel, \$4.75 to \$5.50; No. 2 lump, \$5.50 to \$6.50; ground in bulk as low as \$9; No. 1 and No. 2 ground, \$10 to \$11 per barrel; extra No. 1, \$11.40 to \$12 per barrel. According to Burchard¹ the price of fluorspar in Colorado varies according to calcium fluoride and silica content. The spar is hand cobbled gravel. The prices are: for 80% calcium fluoride and not exceeding 15% silica, \$5; for each per cent of calcium fluoride additional, 20c., so that 85% brings \$6 and 90% \$7 per short ton. Fluorspar for foundry purposes retails in quantities from 50 lb. to ton lots, usually barreled; crude from \$10 to \$20 per ton; ground \$20 to \$32 per ton. The smaller glass and enamel companies also purchase, at times, in small lots of from one-half to five tons. Specimen fluorite in one instance sold at \$60 per ton.

Illinois producers have, in certain instances, cut prices regardless of cost, to meet English and other competition, hence their average prices have been lower in some instances than those of other States. This condition cannot last much longer. The Kentucky shippers have been handicapped north and east of the Ohio river by a difference of 20 to 80c. per ton in freight rates. The low value of the Colorado product at the mine is explained by its high silica content and the high cost of haul, which Burchard writes,² is possible because of proximity to market (Colorado Iron & Fuel Co., Pueblo, Colorado). The Arizona product is handicapped by its distance from available markets.

The sources of competition that fluorspar must meet are three in number: (1) limestone flux, (2) imported fluorspar, and (3) cryolite and by-products. The production in 1907 of limestone flux amounted to 17,609,537 short tons, while in 1908 (an off year in the production of iron and steel) it fell to 10,710,737 tons. Of the total production over 90% is used in the making of iron and steel, the remainder being largely used in lead and copper smelting, about 4% for the former and 5% for the latter. The average price of limestone flux is 44 to 45c. per ton. By the use on an average of 3% of fluorspar per ton of limestone flux used (the percentage would be higher for dolomite, lower under certain other conditions)³ better results may be obtained without material increase in cost, since the combination of fluorspar and limestone makes a more powerful flux, reduces fuel consumption, and acts as a detergent, yielding metal of better quality; in addition, it means the handling

of less raw material, reducing the amount of storage space and labor required. Lead ore containing 5 to 10% fluorspar shipped from the Kentucky-Illinois district is not assessed a penalty, for the fluorspar is distinctly an advantage to the smelter as a flux. In copper smelting it is also an advantage. It will be seen from these figures that the legitimate increase in demand for fluorspar may readily grow to be ten-fold what it is at present. It may be interesting to note that the Fairview mine has reached a depth of 460 ft. The Nancy Hanks incline has been sunk to 340 ft. and is said to show a 9-ft. vein of No. 1 fluorspar.

The amount of fluorspar imported (chiefly from England) has been variously estimated from 30,000 to 100,000 tons annually. The average demand for domestic fluorspar has been about 37,000 tons annually. The tariff should increase this demand by at least 85% of the amount previously imported, through the exclusion of that much of the imported fluorspar. The tonnage reported quarried and mined in England from pits deeper than 20 ft. in 1907 was 49,551 short tons from Durham and Derbyshire, and in 1908 it was 38,250 tons from Durham and Midland. Since there is no law enforcing the giving of statistics for minerals obtained at less depths than 20 ft., the amount of fluorspar obtained from old dumps, far larger in quantity than the other, is not known, and it is this product largely that has entered so strongly into competition with domestic fluorspar. American fluorspar can be used for all purposes to which cryolite is put at less cost and with as good or better results, except the manufacture of sodium salts, for which the bulk of that imported is now used. The result is that the importations of cryolite have materially decreased since 1903, the importations in 1908 amounting to only 1259 tons. A small amount of by-product fluorspar (60% calcium fluoride) is obtained in making the sodium salts.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

S. L., Oasis, California: Specimen in massive white barite.

E. L., Lucky Boy, Nevada: Quartzite with scales of green chlorite.

W. W. R., Stewart, British Columbia: No. 1, brown massive limonite coated with the earthy yellow ochre; No. 2, yellow ochre.

J. S. L., Ibapah, Utah: No. 1, limonite with a bright iridescent coating, possibly due to slight alteration of surface; No. 2, rhyolitic lava; No. 3, an altered feldspar porphyry.

H. F. L., French Gulch, California: No. 1, an altered porphyry containing quartz and feldspar crystals in a serpentine base; No. 2, a quartz breccia consisting of quartz and chalcedony pebbles and fragments with an earthy silicious cement.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Records in Tunnel Driving.

The Editor:

Sir—Referring to your issue of October 30, page 590, in an article on 'A World's Record in Tunnel Driving', it is stated, in reference to the Los Angeles aqueduct, that the best previous known American record of speed for double-shift work was that made on the Gunnison Reclamation tunnel in March 1906, when a distance of 810 ft. was driven. In this connection, I would say that George W. Jackson, Inc., in the construction of what is known as the South West Land and Lake tunnel, a part of the Chicago Water Works system in the southern part of this city, has made a record of 464 ft. in 27 days, working one shift. In this work shots were fired by electricity, and it is not my understanding that a special effort was made for a record, since there was plenty of time to finish the work.

Chicago, November 3.

Metal Losses in Copper Slags.

The Editor:

Sir—I am glad to observe that J. Parke Channing has taken interest in points suggested by the data I recently published in an article on the 'Metal Losses in Copper-Slags', and I sincerely hope that he and others will endeavor to collect and publish further information on these matters of high technical importance. The slags I submitted to examination came from both blast and reverberatory furnaces, making first copper matte of usual grade, namely, 25 to 50% copper. Both classes exhibited similar deficiencies in the ratios of the precious metals to the copper contained by the slag and matte respectively. That is to say, the slags contained less silver and still less gold than should have accompanied the copper of the slag if this copper had all been of the grade of the matte simultaneously occurring in the copper-smelting operation. I did not think it worth while to commence the enquiry by investigating converter, refinery, or black copper slags.

As stated in the paper, the facts observed leave room for belief that some of the copper of the slag may have been existent as silicate. Mr. Channing's suggestion that some of the silver might be in an oxidized form is worthy of investigation. I have no data that would throw much light upon this point. Such as I have, and some will be published later, show that in the ordinary migrations of copper through a cooling mass of slag, or in its precipitation by special methods of fusion, the silver follows the copper. It is well known, for instance, that a bar of lead bullion does not contain its silver equally distributed. The outside contains more than the inside. This is a case of what I have mentioned above as 'migration' in cooling.

In the same manner the shells of slag formed in slag-bowls contain more copper than the inner liquid portion. In cases I investigated, the copper in the shells was not uniformly distributed through the shell. It varied according to position, but the variations of the silver follows the variations of the copper. It looks like a case of molecular segregation in which the three metals, copper, gold, and silver, behave similarly. Circumstances alter cases. I did not observe a falling off of 40% in the copper of the slags when changing from oxidized to sulphide charges in blast-furnace work, as noted by Mr. Channing. I cannot help thinking that the temperature of the slag formation may affect the slag in its power of retaining copper.

LEWIS T. WRIGHT.

San Francisco, November 16.

Ely Central.

The Editor:

Sir—Ely has been quite excited about the attack on Ely Central. The article was apparently inspired by the Nevada Consolidated, which wants the ground between its steam-shovel pit and the Ruth mine. The Nevada Consolidated is getting close to the Ely Central ground in the pit. The two bore-holes, the results of which are quoted by *The Engineering & Mining Journal*, were stopped on account of the caving of the hole. The last one was only finished on Tuesday of last week, so the results must have been telegraphed to New York. The line between the rhyolite and the porphyry is marked by a fault which has a dip to the east between 20 and 25°. The last bore-hole struck the ore at 165 ft. and was in ore when it stopped at 335 feet.

Assuming the continuance of the same dip of the fault to be 20° or more, which is what is claimed, then for the bore-hole above mentioned to have struck ore at 165 ft. means that this was above the fault. The Nevada Consolidated has taken about 25% of its ore from under the rhyolite and has removed about 250,000 yd. of rhyolite overburden. I heard the drill runner tell about striking this ore at 165 ft., and I also heard him say that the hole gave an enormous amount of trouble on account of caving ground. This, no doubt, diluted the samples. In any case, many holes in the district show low percentages of copper for a considerable depth, and then even up the average by better-grade below, or may be low-grade all their depth. I saw the sections of all the Giroux company's bore-holes. The United States Geological Survey has been at work in the district all the summer and has found an area of porphyry that crops on the east side of the Ely Central ground from under the rhyolite just west of a narrow outcropping of limestone between it and the Star Pointer shaft of the Nevada Consolidated. The claim has always been made that the rhyolite was a dike. The evidences that it is a flow are unmistakable. All around the edges volcanic breccia and obsidian are found. Later disinterested geological study has resulted in estimating the porphyry area on the east end of the Ely Central ground as being about four acres in extent.

No one can see into the ground, and the statement

made by *The Engineering & Mining Journal* that the bore-holes in the rhyolite have not found ore is untrue. Nine have been put down, according to F. S. Pheby, the general manager for the company. The rhyolite at present existing is only a remnant of the sheet that covered the surface, and the whole question is whether the enrichment of the porphyry took place after the erosion of the present exposed areas, or before. It does not seem reasonable to think that it took place since the erosion, and on this basis there are as good chances of finding ore in the Ely Central ground as there were in the Nevada Consolidated when Mark L. Requa took up the property.

The Engineering & Mining Journal derides the limestone deposits. If they are correct, then the Cole-Ryan people are idiots to put so much money into limestone claims. Cole is buying up every bit of limestone country in the district that he can get where it shows any jasperoid. The ore is found close to the contact of the jasperoid (silicified limestone) and the limestone. The Giroux has a large tonnage of ore running from 10 to 15% copper. The Ely Consolidated has opened up what promises to be a good mine in the limestone, having found copper pyrite and also massive pyrrhotite carrying copper. All of this ore contains gold and silver of good assay values. From \$6 to \$7 per ton is claimed. I have no hesitancy in stating that I consider the chances of finding a mine on the Ely Central as extremely good. The Ely Central people, I understand, are going to put down some bore-holes in the porphyry zone to prove whether the ore exists or not. This should put an end to the controversy for all time.

Calculation of Blast-Furnace Charges.

The Editor:

Sir—In your issue of November 13, Percy E. Barbour has made some observations on the calculation of blast-furnace charges, and has given a charge calculation for pyritic copper smelting. He has brought out some interesting facts on the neglect of this necessary preliminary, due, as I believe, often from the apparently formidable undertaking, when as a matter of fact, once learned, its details can be carried in mind, and such computations can be made without reference to notes and formulas.

As to the first excuse by Mr. Barbour, namely, that the charges are put on the furnace before results can be got from the laboratory, this might be indeed true; but in any works where the ore is sampled it should be possible to get results soon enough for such use. 'Where there is a will there is a way'. In copper smelting, quite differently from silver-lead smelting, a great variation in slag composition is permissible, and hence has risen a carelessness in the preparation of the charge. Nevertheless, there is no reason why a slag should not be run which shall on the whole be the most satisfactory and profitable. As regards the practice at the Garfield works, there is no question that the officials are well acquainted with computation of charges, and, if they have adopted another system, it is because they are using a charge composed of two or three ores of

approximately the same composition. Hence, with a determination of the resultant slag, it should be possible to do good work. Even when a charge has been computed, the slag which is produced should be controlled by the eye as well as by analysis; and this is applicable to silver-lead charges also, though such control in this latter case calls for long training and continued close observation, controlled by results from the laboratory. In fact, today we find but few metallurgists who depend upon the physical examination of such slags, because of the difficulties involved in so doing. In addition to the excuses already given, I have had it stated to me that the material of the charge varied so that a charge calculation would not hold good. Indeed, careless bedding, careless weighing, and variations in the fluxes and fuel, reveal themselves by important variations in the slag and in its cleanness.

Referring to the singulo-silicate slag, which Mr. Barbour proposed to use, we find in pyritic practice that the metallurgist is chiefly anxious that his slag should carry specified quantities of silica (in this instance 44%), and that the bases go as far as possible with the addition of no more dead limestone flux than needed. The total of SiO_2 , FeO , and CaO , adds up in the present case to 92%, while in practice the sum varies between 85 and 90 for Utah ores.

The charge calculation, No. L 16, assumes a loss of sulphur by volatilization of 85%, a figure higher than my inquiries have warranted. Again, no allowance has been made for sulphur entering the slag, and since this will approximate 1%, there is 28% of sulphur so produced. Taking the figures as given in the article, there would be 29% of sulphur in the matte, while this element in practice commonly amounts to 23 to 24. Copper matte is so complex a compound that one cannot figure its composition from the atomic weights. Thus not all the copper is combined as Cu_2S , nor is the iron present altogether as FeS . For a discussion of this subject, I would refer to a paper by Charles H. Fulton and I. E. Goodner in the *Bulletin of the Amer. Inst. M. E.*, November 1908, p. 859, or to the synopsis of the same in the 'Mineral Industry', Vol. XVII, p. 276. No allowance has been made for the copper which goes into the slag, in this instance 0.3 to 0.5%, or from 10 to 14 lb. This, taken from the total weight of the copper present, would leave only 20 to 22% in the matte instead of the 27% given. I would also note that no columns are left for the percentages of moisture and for the wet and dry weights, respectively. Hence if ore 'B' contained 5% of moisture its scale-weight should be 1260 lb. in place of 1200 lb. as given.

I have given in my work on the 'Metallurgy of the Common Metals', the charge-calculations for iron, silver-lead, and copper charges, based upon the trial method, which I have found practically the most used by smelter men. Since, in the final summing up, this computation is used to check the results, why not use it from the beginning? It is a practical method, and, in the hundreds of calculations I have made, has proved to be the most satisfactory.

L. S. AUSTIN.

Salt Lake City, Utah, November 18.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The Federal mining law does not extend to Texas, Porto Rico, nor to the Hawaiian Islands. The Philippine Islands have a special Federal Act relating to mines and mining.

The purpose of the law in requiring placer locations to conform as nearly as practicable to the rectangular system of the public surveys is to prevent 'shoe string' locations and carving the public domain into irregular shapes. A placer location should be rectangular in form even when upon unsurveyed land.

Silver chloride is nearly insoluble in water. When kept in contact with water three hours, traces will go into solution. When one part of silver is precipitated as AgCl in the presence of one million parts of water, a slight bluish tint is observed from dissolved AgCl. A distinct precipitate of AgCl does not fall until 4 parts of Ag are thrown down as AgCl in a million parts of water.

Chains may be tested as to defects by heating on a forge to dull red, and annealing by being allowed to cool slowly. After such treatment flaws, strained or elongated links may be readily detected. The safe working-load of a chain in tons may be found by squaring the number of eights of an inch in the side of the link, and marking off the last right-hand figure as a decimal. Thus a $\frac{3}{8}$ -in. chain would have a safe working-load of 0.9 ton.

Guano to the amount of 12,000,000 tons has been exported from the Chincha islands, off the coast of Peru. The exportation at present, amounting to 60,000 tons per annum, comes from the islands of Lobos de Tierra and Lobos de Afuera, situated off the coast of northern Peru. Many other islands contain deposits of importance. The nitrogenous constituent of the guano extracted today is said not to be so high as that in the great deposits formerly worked.

Luzonite is a name given to a variety of enargite occurring in the island of Luzon, in the Philippines, where it contains 47% copper. At Mancayan, district of Lepanto, Luzon, it occurs in copper veins in which the order of deposition of the minerals has been quartz, pyrite, enargite (luzonite), quartz, tetrahedrite, and barite. Enargite is a primary mineral at many places, as in the copper mines of Butte, and Tintic. The composition of enargite is expressed by the formula Cu_3AsS_4 . It occurs in large masses at Morococha, Peru, at an altitude of 15,000 ft. above sea.

Tungsten yields to magnetic concentration, and may be readily separated from its ores by a machine of the Wetherill type. In practice the crushed and sized ore is passed first over a belt under magnets in which a field is developed by a current of less than three amperes. This removes any oxidized

iron products and minerals rich in FeO , such as garnets, chromite, and so forth. The residue is then passed through a second machine taking current at from $3\frac{1}{2}$ to 4 amperes, which lifts out the wolframite. Cassiterite may thus be freed from wolfram also. Concentration by ordinary methods should precede the magnetic separation.

Silver-lead mines were operated by the Chinese in what is now the Sterne valley, Burma, in very early times. Active smelting operations were carried on here as late as a century ago, the smelting being done in low shaft-furnaces. Immense slag dumps remain, which are being re-smelted in modern furnaces. Some of these dumps contain as much as 100,000 tons of slag. A typical sample shows a composition of silica 8 to 12%, iron and alumina 8 to 9, lead 48, zinc 16, sulphur 3, and silver $2\frac{1}{2}$ oz. per ton. The lead is present in the slag mainly as PbO , less than 3% being in the form of prills.

Radio-activity of natural waters is now recognized as an important feature. The curative properties of many depend largely upon the radio-active substances present. That is why artificial mineral waters, of identical chemical composition do not produce the same beneficial results. The activity of the thermal waters in the Yellowstone National Park is particularly great, reaching 834 electro-static units in the spring near Clepsydra geyser. The Karlsbad waters vary in different springs from 2 units to as high as 94. Many European mineral waters have high radio-activity.

Setting of portland cement is a phenomenon not fully understood, but it is assumed that the action is brought about by the hydration and crystallization of the calcium aluminates, which occurs with great rapidity on adding water to the cement. This constitutes what is known as the initial set. Following this occurs hydrolysis of the calcium silicates, the latter being slowly decomposed and broken down into the simpler mono-calcium silicate, with the liberation of calcium hydrate. As this forms in excess it crystallizes out of the solution. This cycle of operations continues for long periods in the process of hardening of cement.

Monel metal, a new alloy of nickel recently put on the market, contains 68% of nickel, 1.5 of iron, and 30.5 of copper. It is silver white and takes a brilliant finish which it retains indefinitely. It is said to possess a tensile strength about 25% greater and an elastic limit about 50% higher than the best rolled steel, and it has, besides, the additional quality of incorrodibility. The mechanical possibilities open to such an alloy are endless. For example, the small cast propellers used in hydroplanes or high-speed motor boats are subjected to enormous strain. Some propellers used in such boats make 1500 to 2000 revolutions per minute. The strain on a blade 16 in. long, with a pitch of 40° , and with the edge of the blade thinned down to $\frac{1}{8}$ in., is so great that an extraordinary metal is required for this use. Manganese bronze bends at the blade tip and becomes useless, but monel metal has been fully tested in such service and proves to be absolutely rigid.

Special Correspondence.

LONDON.

Rhodesia.—De Bavay Flotation Process. — Otavi Mines and German Southwest Africa.—Globe & Phoenix.

The twentieth anniversary of the founding of the British South Africa Co. occurred October 29. The event was allowed to pass by without any public notice, not even the Englishman's proverbial dinner. Rhodesia is commonly held to have been scarcely a success, but such a view is not quite fair to the country. It expresses a reaction on the part of shareholders in the chartered company, who were promised all sorts of impossibilities in the way of dividends and appreciations of capital. If the country itself be considered apart from the unfortunate joint-stock enterprise, progress has really not been discouraging. It is true that no bonanza mines that would pay without railway communication have been discovered, but gold production from low-grade mines has been substantial, if not profitable to investors. There are, moreover, possibilities in the way of copper, lead, and zinc. When it is remembered that until 1890 the whole country was under the despotic sway of Lobengula's uncivilized hordes, the change that has been effected is more apparent. The number of miles of railway open ten years after the granting of the charter was 252, and at the end of the second decade had been increased to 1494, not counting the 506 miles in Bechuanaland and Cape Colony constructed by the Rhodesia railway company. By the end of this year a further 130 miles will be opened to the Congo border, making a total of over 1600 miles in Rhodesia. The total value of gold produced up to 1898 was £83,052; during 1908 it amounted to £1,678,000. It is also worthy of note that from 1895 to 1908, out of a total value of £15,000,000 of imports, £9,000,000 represented purchases from the British Islands. According to the census, taken in September 1907, the European population of southern Rhodesia numbered 14,007; and since that date the annual rate of increase has been much larger than in former years, and the population today probably exceeds 16,000.

The De Bavay flotation process is not so well known as some of the others of the same class. It depends solely on surface tension of water, and according to experts who have thoroughly tested it at Broken Hill, can be operated cheaper than any other. Recently the plant has been rebuilt on a larger scale and important contracts have been made for the treatment of zinc-tailing. The company known as the De Bavay's Treatment Co. has been re-organized under the name of Amalgamated Zinc (De Bavay's), Limited. The capital of the company is £500,000 in shares of £1 each. Of these 247,500 go to the shareholders in the De Bavay's Treatment Co., and 122,500 are being offered to the public. The issue was largely over-subscribed in Australia and London. The company acquires the old and new mills and large amounts of old and current tailing. The works and plant are situated on the property of the North Broken Hill Mining Co. The old mill treats 1800 tons per week, and the mill in course of erection will treat from 6000 to 7000 tons per week. The first half of the new plant will be completed by the end of this year and the remainder in March or April next. The cost of the new mill will be about £100,000. The stock of dump-tailing acquired comprises 100,000 tons from the North Broken Hill mine, already paid for; 370,000 tons from Block 10 mine, partly paid for; and 100,000 tons from Broken Hill South Silver mine, to be increased to 150,000 before the new mill starts operations. The last-mentioned tailing will not be paid for in cash, but will be worked conjointly. Contracts have been made with the North and South companies for their output of tailing, in the case of the first for ten years, and of the second for seven years, which may be extended under certain conditions to ten years. The yearly amount from the North will be from 120,000 to 160,000 tons, and from the South 160,000 tons. Contracts have already been made for the disposal of the whole of the concentrate produced during the ten years. During the first half of 1909, the old mill treated 47,370 tons of zinc tailing, averaging 18.3%

zinc, 3.7% lead, and 3.4 oz. silver, and produced 14,646 tons of zinc concentrate assaying 48.6% zinc, 6.1% lead, and 5.8 oz. silver, together with 256.5 tons of lead concentrate assaying 54.6% lead, 13.8% zinc, and 23.4 oz. silver. The profits were £17,427, with zinc at £21 12s. and lead at £12 10s. per ton. The separation into zinc and lead concentrates is not as perfect as it might be, and the lead product does not appear to be especially valuable.

Many improvements, however, have been made, especially in the treatment of leady tailing from Block 10, and these will be incorporated in the new mill. In future the lead content of the zinc concentrate will be decreased, and in the lead concentrate the lead content will be increased and the zinc content decreased. The cost of treating North and South tailing in the new mill is estimated at 6s. per ton, and of Block 10 tailing 7s. per ton; the costs in the old mill vary from 6s. 10d. to 8s. 2d. The price paid for the zinc tailing varies considerably from 1s. 6d. to 5s. per ton, and in the case of the South tailing the cost is worked out on a conjoint plan. The figuring of the profits is, therefore, complicated, but the prospectus treats the subject in full detail, calculating the profits with varying percentages and prices of zinc. With zinc at £21 per ton, the yearly profit is estimated at approximately £110,000.

The Otavi Mines & Railway Co., a Berlin corporation, owning the Tsumeb copper and lead mine in German Southwest Africa, and the railway connecting the mine with the coast at Swakopmund, after passing through a troublous youth is now becoming a profitable undertaking. The ore-bodies are rich and extensive, but being complex have presented difficulties in concentration and smelting. Until recently the ore was hand-picked, and the richer portions thus collected were exported. More recently the non-shipping ores have been smelted locally and the copper matte and lead exported. The company was formed in 1900 and the capital is £1,000,000 in ordinary shares, together with 200,000 deferred shares. The first dividend was paid for the year 1907-8, being at the rate of 9% on the ordinary shares, and 4% on the deferred shares. The report for the year ended March 31 has just been issued. The profit on the mining operations was £91,235 and on the railway £122,191, after full allowance for depreciation, renewals, etc. Out of the total profit £110,000 has been distributed as dividend on the ordinary shares and £60,000 on the deferred shares; the board receives a bonus out of profits of £13,333 and the remainder of the balance is put to reserve fund or carried forward. The amount of ore raised was 44,250 tons, as compared with 25,700 tons the year before. Of this 27,000 tons averaging 17% copper, 30% lead, and 12 oz. silver were shipped, and the remainder, 17,250 tons, were smelted locally, producing 3000 tons of lead containing 24 oz. silver per ton, and 3150 tons of copper matte containing 42% copper, 23% lead, and 16 oz. silver. An improved dressing plant is being erected. Hitherto the mining operations have consisted almost entirely of open workings, but it was found desirable a year ago to adopt underground mining below the first level. It is intended to introduce machine-drills before long. Proposals have been made by the German Colonial Office to acquire the railway by purchase, and in all probability the transfer will be made in April of next year. The purchase price will be £1,100,000 and the money so received by the Otavi company will be distributed among shareholders as a return of capital.

In the London letter, in your issue of October 16, reference was made to the case of the Globe & Phoenix mine in Rhodesia, the shares in which had enjoyed a big spurt in the London stock market without the directors publishing any news to the shareholders that would account for the rise. It was generally supposed that those in authority were speculating on their own account without letting shareholders and the public into the secret. The directors have protested against such a construction being placed on their actions, and as they are men of honor their word should be taken. An almost identical phenomenon has been seen in connection with the shares of the Sheba Gold Mining Co., operating in the Barberton district, of the Transvaal. This company did well during the years 1891 to 1898, but has since paid no dividend. In fact in 1904, additional

working capital had to be raised by means of re-construction. During the year ended June 30 last, 96,100 tons were milled, yielding by amalgamation, concentration, and cyaniding, a total of 25,944 fine oz. of gold. The extraction is returned as 87½% of the contents, as compared with 74% a year ago, but the manager, Howard Hill, rightly draws attention to the fact that substantial amounts of rich concentrate were held over from the previous year, and consequently made the increase in the extraction more apparent than real. About a year ago the directors came to the conclusion that work should be concentrated on one or two parts of the property, instead of there being so many scattered workings. This was accordingly done, and the ore is now being drawn chiefly from the Insimbi and Zwartkopje. During the year covered by the report the development did not bring to light any ore of over 7 dwt. value, but since then some important discoveries have been made on the Rosetta property. At the meeting of shareholders held at the end of October, the directors were able to announce that some high-grade ore had been found. At a point only 15 ft. from the surface a vein assayed 15 dwt., and at 40-ft. depth the assay was 24 dwt. over a width of 54 in. Similar assays have been given at other points and there seems a good chance of a valuable orebody being developed. The directors were placed in a false position by somebody on the spot supplying the information to London speculators, who commenced to boom the market before official news was published. The directors properly told shareholders at the meeting that they did not care to publish every promising assay, for in the past there have been many disappointments owing to the rich parts being patchy, and they gave a specific warning in the present case that the new discovery must not be magnified into a bonanza.

TORONTO, CANADA.

Cobalt Lake Litigation.—Hydro-Electric Power Difficulties.—La Rose.—October Production —Provincial Mine Output.

In the now celebrated case of the Florence Mining Co. against the Cobalt Lake Mining Co., claiming, on the ground of previous discovery, a large area of the bed of Cobalt lake, Chief Justice Moss, of Ontario, has issued an order allowing the Florence company to appeal from the adverse decision of successive Ontario courts to the Imperial Privy Council, and approving the security given by a deposit of \$2000. The Government of Ontario, refusing to admit the claim of the Florence company, afterward sold the bed of Cobalt lake to the Cobalt Lake Mining Co. for \$1,085,000 (which in the light of subsequent developments appears to have been a losing deal for the latter company) and, on the Florence company bringing an action, confirmed their title by a special act of the Legislature barring all other claims. The decision of the lower court, given June 15, 1908, was based upon this act, Judge Riddell ruling that "the Legislature within its jurisdiction can do anything which is not naturally impossible and is restrained by no rule human or divine. If it be that the plaintiffs acquired any rights—which I am far from finding—the Legislature has the power to take them away. The prohibition, 'Thou shalt not steal', has no legal force upon the sovereign body, and there would be no necessity for compensation to be given. We have no such restriction upon the power of the Legislature as is found in some States." This judgment was subsequently affirmed by the Court of Appeal. While Judge Riddell's dictum as to legislative powers is undoubtedly applicable to the British Parliament, and presumably to that of Canada, there may be room for the contention that it does not hold good as regards a subordinate body like a Provincial Legislature, and the result of the ultimate appeal will be watched with interest in legal as well as in mining circles, especially as a similar question has arisen in connection with the hydro-electric policy of the Government. It is rather a long story, and I will merely briefly outline its more important phases.

The Whitney government of Ontario came into power largely owing to the feeling that its predecessors had been too subservient to corporation interests, and a considerable section of its following strongly favored public ownership

of public utilities. Early in its career it undertook to supply cheap electric power from Niagara Falls to a number of the principal cities and towns of western Ontario. This was to be done by purchasing the power from the electric development companies already established at the Falls and forwarding it by a Government-owned transmission line to be operated by the Hydro-Electric Commission with a member of the Government as chairman. The Act embodying the scheme, passed in 1906, authorized the Commission to sell power to any municipality which should by vote of the rate-payers authorize the estimates of the cost of the power and specifications, and the terms of a provisional contract. In accordance with this provision, by-laws were passed in many places stating the price which power delivered ready for distribution would cost. After these by-laws had been adopted, the Government changed its plans, declined to set a fixed price at which the power would be delivered locally, and passed a new Act requiring the municipalities to take the power at \$10.40 per horsepower per year at the Falls, and to pay in addition further sums not ascertained for construction and operation of the transmission line. New contracts embodying these terms were presented to the municipalities, and in many cases signed without being submitted to the rate-payers, though in some instances strong exception was taken to this as illegal, and several lawsuits were brought to test the question. Again Premier Whitney resorted to the 'sovereign power' of the Legislature, and Acts were passed in 1908 and 1909 declaring the contracts valid and staying forever all actions pending which attacked the validity of any contract or by-law, or called in question the jurisdiction or authority of the Commission. Extensively signed petitions from financiers, as well as those whose local interests are affected, have been sent to Ottawa urging the Canadian Government to exercise its power of disallowance and set aside this legislation, which is represented as being highly injurious to Canadian credit abroad, but judging from the precedent set in the Cobalt Lake case, it is not likely that there will be any interference from that quarter. Sir Wilfred Laurier having just now troubles of his own in connection with the question of naval defence, will hardly care to raise the issue of 'Provincial Rights', which has in the past caused such long and embittered controversies between governments and parties. But the matter will assume an entirely new phase should the appeal in the Cobalt Lake case prove successful on the ground that the Ontario legislature had exceeded its jurisdiction. Such a decision would mean the overthrow of the whole hydro-electric policy; a much more important and far-reaching matter than the claims of the rival mining companies to a somewhat doubtful prospect.

Cobalt is under a cloud at present owing to the further break in La Rose, which appeared to be slowly recovering itself from the slump caused by the throwing on the market of large quantities of stock held by New York interests when a fresh break occurred early in the month, sending the stock down slightly below par, at about which point it remains. This drop was due to the statement issued by the new president, D. L. McGibbon, of Montreal, and some of the other directors of that city, where the controlling interest is now held, who after a visit of inspection to the properties made a disclosure that startled the public. This statement points out that the La Rose mine is the only one of the properties which can be said to be fairly well developed; that it has been furnishing almost exclusively the money to pay dividends and develop the other properties; and that while on June 1 it still showed estimated ore reserves close on 5,000,000 oz., it was not to be expected that it could furnish for an indefinite period enough to pay dividends at the present rate and to bring the other properties to the productive stage. They therefore decided to reduce the dividend to 8% per year and to put aside an increased amount for developing the other claims. They expressed surprise that so little work had been done on these, and noted that lack of power had caused much delay. Compressed air had been promised by the Cobalt Hydraulic Power Co. on July 1, but it was not expected to be available before January. The most disappointing feature of the

statement, however, related to the Lawson, the main vein of which, known as the 'silver sidewalk', is only yielding low-grade ore at the 88-ft. level. This revelation has had a tendency to weaken confidence in Cobalt generally, as so much had been expected from this vein. The La Rose slump has affected the whole list unfavorably and there are no indications of any immediate recovery.

Cobalt shipments for October amounted to 2356 tons, being 594 tons less than in October 1908. No new shippers have developed, several mines which have been announced from time to time as preparing to make consignments having so far failed to make good. La Rose was as usual first on the list with 717 tons, and Nipissing came second with 440 tons. In cheering contrast to the gloomy features of the situation is the presentation by the Crown Reserve of an extra Christmas bonus of 10% to its shareholders, in addition to the regular quarterly dividend of 6% and bonus of 9%. This brings up the total distribution to shareholders to 70% for the year.

Now that the Ontario Government has sold the Provincial mine and adjacent properties, there is no longer any reason for concealing the facts as to the value of the ore extracted during its operation. In the annual report of the Bureau of Mines for 1909 just issued the figures are given. Three shipments in all were made, two of 46 tons of cobalt ore, which realized \$3289, and one of 24 tons, the silver content of which assayed 783.17 oz. per ton, the consignment, including other metallic contents, bringing \$9027. Under the circumstances it is no wonder the Government determined to sell the mine and was careful not to allow these details to become public.

WASHINGTON.

Alaskan Geological Surveys.—International Map.—Congress and Conservation.—Land Withdrawals.—German Potash Situation.

A. H. Brooks, of the Geological Survey, has just returned from Alaska and announces that while dry weather and other unfavorable conditions have curtailed the placer gold production at Nome, most of the other camps have either maintained or increased their output. It seems probable that the production for 1909 will be between nineteen and twenty million dollars. The low price of copper has not encouraged mining of that metal, but about half a dozen properties shipped ore during 1909. It appears probable that the Alaska copper output for the year will exceed four million pounds. In view of the recognized importance of Alaska's bituminous coal deposits, a detailed survey has been made of the Matanuska field. By the time this important field is reached by the Alaska Central railway, detailed information regarding the distribution and magnitude of the coal deposits will be available. The railway will also afford access to the Willow Creek district, where some quartz veins carrying high gold values were opened in 1908. "Railroad construction," said Mr. Brooks, in speaking of the Chitina copper precinct, "is being energetically pushed on the Copper River railway. Trains are now running 75 miles, and probably 25 more will be completed this fall. This road will connect the copper deposits of the Chitina with tide water on Prince William sound." Detailed geologic mapping of the best developed portion of this important copper district has been completed. A geologic party at Fairbanks has been engaged in the preliminary study of the newly discovered gold quartz of the region. "Although no large orebodies have been found," said Mr. Brooks, "some of the veins assay high and appear to be persistent. Pyrite, arsenopyrite, stibnite, sphalerite, galena, and free gold are found in a gangue of quartz. Prospectors report the occurrence of telluride ores, but specimens tested in the Survey laboratories show no evidence of tellurium. Veins from 1 in. to 12 ft. or more in thickness have been opened at about a dozen localities. Development is chiefly surface prospecting, but some deposits have been followed to a depth of nearly a hundred feet by shafts and tunnels. The indications are sufficiently encouraging to warrant more extensive prospecting." Two important pieces of exploratory work were accomplished, one in the region west of Cook Inlet and one over an area between the lower Yukon

and Seward Peninsula. The two largest lakes in Alaska have been surveyed, Lake Iliamna, about 100 miles long, and Lake Clark, a narrow lake about 50 miles in length. Copper and gold-bearing quartz and a little placer gold have been found in this region, but they have been but little developed. Exploratory surveys in the country lying between the Yukon and Norton bay show that the region extending eastward from longitude 161° holds out but little promise of containing valuable mineral deposits. To the west of this line, however, there are metamorphic rocks which may be auriferous. Geologic work was done by one party in the gold and copper regions of the eastern Kenai Peninsula and important information obtained concerning its geology, geography, and mineral deposits. Measurements of stream flow, in order to determine the quantity of water available for placer mining during the open season, were continued this year in the Fairbanks, Birch Creek, Hot Springs, and Rampart districts, and also in the various placer camps of the Seward Peninsula. Water-power plays an important part in the mining industry of southeastern Alaska. Its utilization will permit the mining of low-grade ores which cannot be commercially exploited by the use of coal. For this reason an engineer of the Water Resources Branch of

Map of Alaska.

the Survey visited this field in order to familiarize himself with the water problems involved and to obtain a basis on which to plan systematic work. Another party spent the summer in carrying reconnaissance surveys from the Yukon to the Koyukuk and thence to the Chandalar. The annual gold production of the Koyukuk among the Yukon camps is exceeded only by that of the Fairbanks. In accordance with the practice of making detailed surveys of the important mining districts, the geologic mapping and study of the ore deposits of the Berners Bay district was completed this summer. This district, though dormant at present, possesses some valuable lode quartz deposits. These surveys were also carried southward to the Eagle River district.

Bailey Willis and S. J. Kübel, of the United States Geological Survey, have started for London to take part in a conference regarding an international map on the scale of 1:1,000,000. The United States Geological Survey has for some time past been engaged in compiling maps of portions of the United States on this scale. The meeting is the result of a resolution presented at the Ninth International Geographic Congress held in Geneva in 1908 by Henry Gannett, of the United States Geological Survey, providing for the formation of an international committee to which should be intrusted the arrangement of details for a closer and more definite co-operation in the preparation of the proposed world-map. This resolution was adopted, and in conformity with its instructions, the British committee has invited the following countries to meet with it: Austria-Hungary, France, Germany, Italy, Japan, Russia, Spain, and the United States.

It is evident here that Congress will be asked by the President to formulate a definite national policy to govern the disposal of the public domain. Mr. Taft, it is understood, will come out in unmistakable language to the effect that the conservation of the minerals and land must be a

matter of law, not of executive action. He devoted a considerable portion of his annual message to this subject. In the meantime, R. A. Ballinger is preparing his first annual report as Secretary of the Interior. In it he will take occasion to reiterate his well known views on conservation and will recommend the passage of certain laws looking toward the protection of the rights of the whole people. Members of Congress are also taking a hand in this troublesome problem, and it is understood that a number of bills have already been drawn up so that they may be presented the opening day of Congress. The Public Lands Committees of both Houses will begin hearings on the subject as soon as Congress convenes. They have plenty of material to consider, for the bills introduced during the last session will come up for report. Among these are several calling for a complete revocation of all withdrawals of public lands. The most notable of these is that of Sylvester C. Smith, of Bakersfield, California, prohibiting the withdrawal of lands by the Executive without legislative sanction. Without waiting for decisive legislation, Mr. Ballinger has just withdrawn from public entry 8000 more acres of land in the States of Montana, Idaho, Colorado, Washington, and Wyoming, and the Territory of New Mexico. The land is thought to be valuable for water-power sites. It is located as follows: 634 acres on Rock creek, Montana; 1627 acres on Clark fork, in Montana and Idaho; 3584 acres on the Gunnison river and tributaries in Colorado and New Mexico; 1498 acres on the Klicitat river in Washington; 200 acres along the Judith river in Montana; and 712 acres along the Green river and tributaries in Wyoming.

Advices received here through the Consular Service are to the effect that the German Potash Syndicate members have quarreled and that the American farmers will benefit by reduced prices for their fertilizers. Owing to the extensive area of the potassium field, covering a considerable part of the Duchy of Brunswick, the province of Hanover, and extending into other States, new mining companies are established every year. When the competition of these companies becomes acute, they are admitted into the syndicate. At recent meetings of the syndicate the quota of a number of new companies was settled and they were admitted. Then arose dissensions as to the allowance to be made to each of the old companies, some of which had concluded contracts with American customers. There are two groups of these mines, one the Schmidtman group, consisting of the Aschersleben and of the Sollstadt mining works, representing what is called the North Trust. The other includes the International Agricultural Co., in the United States, and the Elnigkeitt Mining Works, with those of Westeregeln and Salzdetfurth, forming the South Trust, in the same country. On September 30 a final meeting of the syndicate took place and the proposition of the Schmidtman group for the syndicate to take over certain contracts with American companies for the delivery of 54,000 tons of pure potassium salts at half the prevailing price was rejected, and the syndicate broke up. The Schmidtman group withdrew and also the Elnigkeitt Mining Works. The Westeregeln and Salzdetfurth mines, which had hitherto acted in concert with Elnigkeitt, broke their union with that mine and have remained with the majority of the mines, numbering about fifty. These have resolved to form themselves into a new syndicate known as a 'Kampfsyndikat', or fighting trust.

SALT LAKE, UTAH.

Majestic Sinking. — Red Warrior Ore. — Chief Con. Production.

Alex. Moffett, general manager for the Majestic Mines Co., announces the arrival of the 300-gal. pump at the Harrington-Hickory shaft, and says that it has been installed. The flow of water is not heavy and the new pump keeps the mine drained with little effort. Sinking from the 500 to the 600-ft. level of the property has been begun. Some interesting development is expected. The drills have shown the existence of a much higher silver-lead ore in depth, and the engineers of the company take the view that the richest deposits will come in above the sulphide ore.

The opening of this mine will have a great effect on the future of the Star district. Its workings are the deepest in that district, and a large tonnage of shipping ore has been developed between the third and fifth levels. Since the pump has been installed the management is preparing to make regular consignments of ore to the Salt Lake smelters. From this extraction the company will be able to show a profit above its operating cost.

Sioux Consolidated reduced its regular monthly dividend from 7 to 3c. per share. Its dividend now amounts to \$22,500, and will not be increased until more high-grade ore is opened. Most all of the first-class product to the 400-ft. level has been extracted. The Colorado posted its regular dividend of 8c. per share, aggregating \$80,000. Iron Blossom re-entered the dividend paying division by paying 8c. per share to shareholders, the total distribution amounting to \$79,200. This company has one of the largest estates in the Tintic district. The main working shaft has been sunk 1300 ft., and drifts are being sent from this and the 1100-ft. level to get under the rich deposit that has been opened off the south shaft at a depth of 335 ft. J. Will Knight, the new manager of the mine, says they may decide to continue the shaft to a depth of 2000 ft. should they find the ore continuous. A second deposit of sand carbonates has been opened in the Red Warrior mine. At a point about 60 ft. south from the shaft on the 400-ft. level the orebody has widened, and over 6 ft. of high-grade silver-lead is being mined. The company is making a nice profit on this and is opening other portions of the ore deposit. Driving to the north from this level has opened the ore for a distance of 75 ft. After the ore has been blocked out on this level, the management will sink a winze. Lucien Merritt, president of the company, is visiting the mine, and before his return to his home in Duluth will give orders to have the forces increased and the property opened extensively. The ore being marketed averages \$20 per ton.

Walter Fitch, president of the Chief Consolidated Mining Co., which has a large group of claims in the town of Eureka, reports things in excellent condition. During October he shipped ore that netted the company \$7316, while the November shipments to date will net \$10,000 more. A 50-ton car of ore is forwarded daily. It nets \$25 per ton. The main working shaft has attained a depth of over 2000 ft., and a higher grade of silver, lead, and copper ores occur in the lowest workings. The company is controlled by Boston people. Earnings are expected to become \$50,000 per month within a short time. The mine is in Tintic and adjoins the Centennial-Eureka, owned by the United States Smelting Co. When Walter Fitch was general manager of the United States company properties, he conceived the idea that the Chief ground was valuable. Accordingly he resigned his position and has since devoted himself to the development of the new property. William H. Hatfield, general manager of the Ophongo mine, in Tintic, says that they will increase the shipments from two to three cars per week. This mine was opened only a few months ago. Permission was secured from the Black Jack company to drive a drift from the 300-ft. level into Ophongo ground. A fissure bearing ore was discovered, and the management has opened this ore for a distance of 40 ft. Fourteen mine-cars taken out a few days ago showed ore of an average of 20% copper. Work will soon be started on a new adit which this company will drive on its own ground to cut the fissure at greater depth. With this work completed the management will install a hoist in the adit and sink a winze on the ore.

The inspection recently made by the Utah Copper directors and officers of the mine at Bingham and the mill at Garfield is viewed with a great deal of significance. While this is the regular annual inspection of these properties, one of the subjects under consideration was the recommendation made by D. C. Jackling to add to the present capacity of the mill plant at Garfield. This reduction works is now treating 6000 tons of ore per day, and the new plans, provided they are adopted, will call for an additional capacity of 3000 tons. The new equipment is to be the same as that in operation in the main plant, with the Chilean crushers and vanner tables.

GOLDFIELD, NEVADA.**Production. — Consolidated Development. — Combination Fraction.**

Ore production in the Goldfield district is maintained at a figure varying from \$215,000 to \$235,000 per week, an amount considerably below the normal, owing to the abandonment of the Combination mill, the additional changes in the Florence mill, and the cessation of operations at the Daisy. A new gyratory crusher has been installed in the Florence mill which will hereafter treat 160 to 170 tons per day, and by December 15 the Consolidated, with the aid of six Chilean mills to be installed soon, will be treating 850 to 900 tons per day. The old Combination mill is being dismantled and portions of the woodwork, with which the ore in various steps of the process of reduction has come in contact, have been burned and many thousands of dollars worth of gold recovered from the ashes. In the burning of this wood, a furnace without draft was used in order to prevent loss of the finer particles of gold. The quarterly meeting of directors of the Consolidated Mines Co. was held in Goldfield, November 18, a week earlier in the month than usual, in order that the Eastern directors might return to their homes in time for Thanksgiving. In addition to the regular quarterly dividend of 30c. per share, an extra of 20c. payable January 31, was declared. After payment of these dividends \$1,000,000 will remain in the treasury. J. H. Mackenzie resigned as general manager, and J. R. Finlay was elected to be his successor. Before the end of the year a drift at the 1000-ft. level of the Clermont shaft should reach the vein, which has proved of such vast magnitude and richness at the 860 and 730-ft. levels. The cross-cut at the 1000-ft. level is being driven to the west, toward the Mohawk vein, and the dip of the ore-shoot opened above is toward the shaft. At the upper levels the walls are well defined and regular in direction, the vein trending northeast. At the 860-ft. level the vein is 20 ft. wide and composed of good milling ore. Preparations are now being made to open stopes at this level, from which a considerable tonnage has already been taken in the course of development. Raises are being driven from the 730-ft. level to connect with the workings at the 600-ft. level. One raise has already been completed, and another will shortly be started to connect with the drifts from the bottom of the 50-ft. winze below the 600-ft. level at the south and near the boundary line of the Mohawk and Jumbo. In these drifts large bodies of excellent milling ore have been opened, and near this point a large production is being made from the stopes opened between the 450 and 600-ft. levels. Northwest from the Clermont shaft the 600-ft. lateral has entered the Red Top vein on the Lucky Boy claim and driving is in progress both ways in good ore. A force of miners is still searching for the body of Matt, the remaining victim of the Hampton stope cave. The remains of his companion were recovered recently, crushed between timbers under many tons of caved earth. The Consolidated mill has been treating 650 tons per day and the mill-heads averaging from \$25 to \$35 per ton, with a recovery of about 94 per cent.

No definite information has been obtainable regarding the plans for the future of the Combination Fraction company. Operations at the mine have been confined to cleaning up the ore already broken, and no ore has been treated by the leased mill, although the sampling department of the plant has been in use by the company owning it. Officials of the Fraction company have always been reticent with regard to the orebodies and production, but in an interview only three weeks ago H. S. Stark, the general manager and consulting engineer, declared that good progress was being made, the mill treating 80 tons per day of \$30 ore with excellent prospects for the continuation of profitable mining. The manager stated that in August last, shipments of 100 tons of the best class of ore found in the mine were made to smelters as an experiment, but that the costs of transportation and smelter tolls were so high that it was determined to treat the entire product of the mine in the 20-stamp leased mill. Some time prior to this interview I was assured by officials of the company that monthly net earnings of from \$40,000 to \$45,000 could be relied upon, and on November 5 the Fraction company paid its first divi-

dend of 10c. per share, or about \$93,000, and the announcement was made after the meeting at which the dividend was declared that the company would retain in its treasury a surplus of over \$100,000, but the mill, now closed, with the break of the stock, is creating much unfavorable comment. The statement that the mill is closed temporarily only does not convince, since it is the usual announcement in such cases. George Wingfield, president and owner of the majority of the stock, is absent.

MEXICO.**Pachuca Changes. — Mining Law. — Guanajuato Improvements.**

Pachuca is still in the lime light awaiting the verdict of the Camp Bird, Ltd., with regard to the Santa Gertrudis. At the London Board meeting of the Camp Bird company, the chairman, A. M. Grenfell, stated that: "The net revenue for the year carried forward to profit and loss account was £320,000"; he also stated that as soon as the final report was received from Mr. Frecheville they would call the shareholders together and submit a financial plan, and it was their desire to so arrange matters that the whole of the profit of the new mine would be available for the Camp Bird company. E. P. Merrill, until lately managing director of the Real del Monte Co., at Pachuca, has just retired and C. W. Van Law has taken his place. The appointment was made November 1. Mr. Van Law was for five years general manager for the Guanajuato Reduc-

**Santa Gertrudis Patio, Pachuca.**

tion & Mining Co., but since last January has been consulting engineer for the Guggenheims at their New York office. Robert H. Lyman will continue as assistant general manager for the Real del Monte at Pachuca. In view of the open bids made for Pachuca tanks recently by manufacturers without license from the patentees, it is interesting to note that the Cia. Beneficiadora de San Francisco have discarded these bids and have placed their order for three additional tanks with the owners of the patent, Grothe & Carter, of Mexico City. Two other orders have also been placed, notwithstanding competitive bids. This looks as though these mining companies recognize the patentees' claims, and are willing to pay royalties rather than run the risk of a lawsuit with its attendant loss of time.

The second reading of the bill for the new mining law was recently held in the Senate, and the discussion that has followed does not seem to indicate that any changes of importance will be made from the draft that was passed by the Lower House, and it seems probable that next week the bill will be finally read and voted on, article by article. It will then become law, to take effect January 1910. An immense aerolite was seen to fall near Lagunillas in the State of San Luis Potosí, and a search party, consisting of a corps of students, is to be sent out by the Instituto Geológico to find it. Those who saw it state that it was very brilliant, the flash of light being several metres in diameter. Mexico already possesses two of the largest meteorites ever found.

The Guanajuato Amalgamated Gold Mines Co., which

owns the Jesus Maria, Providencia, Sangre de Cristo, and other mines in the La Luz camp of Guanajuato, was recently in difficulties and in the hands of a receiver. William H. Puffer was appointed manager and as a result of better and more economical organization and closer saving in the mill, he has been able to pull the company out of its difficulties, the net return per month now amounts to about \$20,000, with the result that arrangements have been made with the creditors and the receiver has been dispensed with. The mill is equipped with 100 stamps, concentrators, and a cyanide plant; a filter plant will be added soon. At present milling from old dumps only is being done. These contain about 300,000 tons of ore. The Guanajuato Consolidated Mining & Milling Co. is now giving net returns of over \$50,000 per month. The company also controls the Carmen-Guanajuato Gold Mining Co., which recently erected a small but complete milling plant having a capacity of about 50 tons per day. This plant is equipped with rock crushers, stamps, concentrators, tube-mills, and a cyanide plant, the whole being electrically driven. The Guanajuato Reduction & Mines Co. has built an electric tramway to transport ore from the old Mellado and Rayas dumps to the mill. Plans are being made to open up the old mines.

The San Miguel Gold Mining Co., a Pittsburg concern, which owns some 400 pertenencias of gold-quartz properties in the Yaqui district of Sonora, has not developed on a large scale during the last few years owing to the Yaqui trouble. Since that is now settled, the company is pushing work actively. A stamp-mill with amalgamation and concentrators, with a capacity of 30 tons per day is being erected. It is expected that milling operations will commence in January.

NEW YORK.

Industrial Activity.—Copper Surplus Decreasing.—Mine Sales.

A new era of constructive enterprises seems to be at hand. The talk of the formation of the copper 'trust' seems to have cleared the atmosphere of all doubt that the panic is over. Second only in importance to the copper combination is the purchase of the control of the Western Union Telegraph Co. by the American Telephone & Telegraph Co. It is thought that the Postal Telegraph Co. will come into or be forced into the new combine. The Wells Fargo Express Co. is to declare a dividend of 300% and increase its capital from eight to twenty-four millions.

The news of the week has been all copper. Many stocks have sold up to new high records in local markets. Amalgamated has been the leader and the entire list of coppers has been exceedingly active at prices much higher than ruled thirty days ago. By no means all of the activity has been limited to the share market. Metals also have been active and the last few days have seen buying in large amount. Sales of some sixty millions of pounds of copper have been reported this week, and it is quite evident the bugaboo of a surplus is to be finally routed. Fractional advances in price to 13¼ and 13½c. are reported, and the long looked for 14c. copper market may be nearer at hand than was thought possible a few weeks ago.

The directors of the Development Company of America have announced that they have bought for the company, the properties of the Saddle Mountain Mining Co., in the Christmas district between Kelvin and Globe, Arizona. They have also obtained an interest in the properties of the London-Arizona Co., controlled by Charles E. Finney. The Development Company of America numbers among its directors, Frank Murphy, president of the Phoenix & Eastern railway, a feeder of the Santa Fe system; B. P. Cheney, a director on the Santa Fe, and other prominent men of like calibre. The Cactus Development Co., which has options on the ground of the Arizona National Copper Co., near Globe, Arizona, is expected to exercise its options about January 1. The Cactus is controlled by Boston and Duluth people, several of the directors of the Calumet & Hecla being interested. The Cactus enterprise is an especially interesting one and fraught with much importance to the copper world, because it marks the first real plunge of the conservative Calumet & Hecla crowd into the Arizona copper fields.

The Utah Copper crowd is said to have taken an option on a controlling interest in the Ohio Copper Co. If the option is exercised the new combine probably will have entire control of the Bingham camp, as in addition to Utah Copper and Ohio, both Boston Con. and Utah Con. are said to be marked for inclusion. The Hedley Gold Mining Co. is experimenting with its 40-stamp mill with a view to reducing tailing losses. The property is a gold mine in British Columbia and was taken over by the present company from an exploration syndicate made up of United States Steel Corporation officials and a group of capitalists who are prominent in the Cole-Ryan enterprises. A mining engineer of New York, who is quite heavily interested in the negotiations now pending for the purchase of the Santa Gertrudis y Guadalupe by the Camp Bird, Ltd., says that he has good reason to believe that the deal is to be consummated. The same authority states that the El Oro people expect to exercise their option on the La Blanca, which option the Camp Bird was supposed at one time to have secured.

BUTTE, MONTANA.

Re-Organization of Amalgamated Subsidiaries.—Sale of Stores and Hotels.—Development of Right Bower.

A re-organization of the Amalgamated subsidiaries is under way to establish a basis for the exchange of stock in the big merger of copper interests that is forming. The lumber interests of the Amalgamated have been incorporated in a concern called the Big Blackfoot Lumber Co., capitalized for \$25,000,000. The company succeeds the Big Blackfoot Milling Co., which is capitalized for \$1,000,000, of which \$700,000 only has been issued. The lumber business of the Amalgamated outgrew this capitalization long ago. It is said that the actual value of the property in the new corporation will inventory between \$40,000,000 and \$50,000,000. The charter under which the new company is incorporated is broad. The directors are all Amalgamated officials—John Gillie, Roy S. Alley, C. F. Kelley, H. A. Gallwey, and L. O. Evans, all of Butte. Mr. Kelley, who is chief counsel of the Amalgamated company, has been in New York for some time in consultation with higher officials relative to the organization of the copper merger. It is likely that other interests of the Amalgamated company, now in low capitalized companies, will be re-organized and put into larger companies. This will probably be true of the coal interests especially, which are said to be worth fully \$50,000,000. While the Amalgamated has been re-organizing some of its interests, such as are closely identified with mining, it has also gradually got rid of others that have not been necessary to mining. All of its mercantile and hotel business has now been sold. The company once owned large department stores at Butte, Anaconda, Missoula, Hamilton, and elsewhere, and in taking over the interests of the late Marcus Daly it acquired hotel properties at Anaconda and Hamilton, which have also been sold. It has been the recent policy of the Amalgamated to confine the work to mining and kindred industries and to leave the mercantile and hotel business to others. The fact that the company maintained such establishments in rivalry with private individuals and small companies has always stirred up much feeling against the big company.

The Anaconda Copper Mining Co. is developing another big mine in the Butte district, called the Right Bower. It is situated on Anaconda hill, just east of the Butte-Ballaklava mine. When the latter opened three or four big and rich copper veins the Anaconda company concluded that the Right Bower, which carries the extensions of some of the Butte-Ballaklava veins, was worth exploring. A shaft has been sunk to a depth of 600 ft., the greatest depth allowed by the laws of the State without a connection with another outlet, and a level opened into the Mountain Chief mine, another Anaconda property. Three large veins, 6 to 15 ft. wide, were found in this level. The connection with the Mountain Chief workings has been completed, and driving is being done on the veins. The ore taken out in the course of development is of high grade, and the miners say the Right Bower will develop in a rich mine.

General Mining News.

ARIZONA.

COCHISE COUNTY.

On the Reider claim, in the Paradise district, the shaft is down 60 ft. on the vein, the ore averaging 4% copper. —The California & Paradise company, which recently took over the Leadville group, is to install a power plant, hoist, and No. 5 Cameron sinking pump.

GILA COUNTY.

A recent shipment of five tons from the Monte Christo group, in the Copper Hill district, assayed 17½% copper with 25 oz. silver per ton. The claims adjoin the property of the Arizona-Michigan Mining Co., and are under lease to John Sherwin. —Between 40 and 50 tons per month of silver ore, with a small amount of copper, is being shipped from the Centennial group, six miles east of Globe, to the Old Dominion smelter, by W. M. Davis and Harry Zschoegner, the lessees. The ore is being mined from a stope opened near the bottom of the winze sunk from the drift on the 300-ft. level. —Both cross-cuts on the 500-ft. level of the Telfair shaft of the Arizona-Michigan property are in a hard diorite. The company is doing considerable work on the Blackbird, Defender, and Old Dominion claims. S. W. Clawson is manager. —The Cordova company, in the Miami district, has started a shaft on the line between the Jennie and Osceola claims, about 250 ft. from a drill-hole on the Inspiration group, that passed through 200 ft. of concentrating ore.

MARICOPA COUNTY.

The Vulture mine, situated southwest of Wickenburg, from which point supplies are hauled by wagon, has been famous since 1863, and is reputed to have produced \$16,000,000. It had been idle for several years, but in 1908 was taken over by the Vulture Mines Co., and W. Spencer Hutchinson placed in charge of the work. Five bulletins have been issued since the new work has taken up. These relate that the old shaft was found in good condition, that a local water supply has been found, oil adopted for fuel, and distillate engines installed, 2513 ft. of development accomplished, 20 stamps of the old mill put to work, and important ore reserves established. It is stated that the output of the present mill will meet operating expenses, and that an average of \$11 per ton has been maintained without touching ore reserves. A new mill is being planned.

MOHAVE COUNTY.

A. J. Sayle, consulting engineer at the Giroux mine, near Ely, who was sent into the new districts near Bill Williams Fork to report on some prospects for the Amalgamated interests, was impressed so favorably with the general showing of the entire district that he not only at once secured the property in question, but located 20 additional claims for himself and associates. —At the Ruth mine, in the San Francisco district, the faulted vein was found in a cross-cut on the 100-ft. west drift 45 ft. from the shaft. Two feet of the portion of the ore already cut are said to assay over \$100 per ton. —The South Gold Roads group of three claims, owned by E. A. Shaw and associates, has been bonded by a company of Indianapolis men. The group adjoins the Gold Road mine and some good ore has been found on the ground. —In the Carter mine sinking has been resumed in the shaft and will be continued to the 260-ft. level. —J. H. DeWaide, of Oklahoma, and S. R. Porter, of Los Angeles, visited Mineral Park where they have a force of men at work in the Keystone mine. It has been decided to equip the mine with steam hoist and drills. —The Tennessee mine, at Chloride, owned by James H. Hurin and associates, has been bonded by L. D. Godshall, manager of the Needles smelter, presumably for the United States Smelting & Refining Co., for which he has made all his recent purchases. —At the Eureka mine in the new Walnut Creek camp, five miles east from Drake, on the main line of the Santa Fe, and about ten miles from Kingman, L. M. Worton, the manager, is installing a pump, hoist, and air-drills preparatory to sinking 200 ft. from the

present 50-ft. level. —Louis Lusk and C. A. Cobb, of Spokane, have just purchased five claims between Walnut creek and the Bi-Metal mine, and have started work under the direction of A. J. Hamme. —At the annual territorial fair at Phoenix first place for the best all round mineral exhibit was awarded Mohave county.

PIMA COUNTY.

A 4-ft. vein of high-grade ore has been found on the property of Dan Johnson, west of Greaterville, in the Santa Rita mountains. About 300 ft. of development work has been done on the group.

PINAL COUNTY.

The Santa Rosa group, east of Silverbell, has been bonded to Albert C. Wandel and associates of Nevada. There are 25 claims in the group on which a 100-ft. shaft has been sunk opening some good copper ore. The new operators will take over the property and commence development at once.

YAVAPAI COUNTY.

At the Shylock mine, six miles east of Dewey, complete electrical equipment has been installed and a force of men put to work cleaning out the main shaft preparatory to sinking. At present it is down 610 ft. and the company plans to sink to the 1000-ft. level and cross-cut the ore which on the upper levels has been from 35 to 50 ft. thick.

Bradshaw Mountains, Arizona.

—E. T. Taylor and H. P. Dyson have purchased the interest of N. J. Griffin in the Capitol North claim, in the Walker district. Several runs of the ore have been made in the Pine Mountain mill with satisfactory results. —A rich shoot was opened in the Zero North mine, south of Prescott, by John Quelico, who is operating the property under lease. The ore was opened by a drift being run on the old Zero vein when in 280 ft., giving 175 ft. vertical depth. The mine is credited with a production of \$40,000 worth of gold and silver ore though opened only to a depth of 200 feet.

YUMA COUNTY.

At the Blue Bell mine, near Swansea, the company has 200 tons of \$25 ore on the dump, with a large amount of similar material blocked out in the mine. —All the wood work in the smelter at Swansea is being replaced by structural steel, and the work of enlarging the plant to a capacity of 700 tons per day will be under way in a short time.

CALIFORNIA.

CALAVERAS COUNTY.

The adit on the property of D. Porteous, at West Point, cut some excellent ore. —At the Crown Point mine the drift is being driven on a 3-ft. vein that assays from \$6 to \$8 per ton. —There are 40 tons of high-grade ore on the dump of the Bouvard Extension mine, operated by Smith & Thompson. —J. Sterling & Co., have erected cyanide tanks in the canyon below the old Jenkins mill and will treat the old tailing. —At the Yellow Aster mine, Congdon & Carlton have cleaned out No. 2 adit and resumed work there.

—High-grade ore has been opened by a shaft at the M. R. G. mine at a depth of 40 feet.

MARIPOSA COUNTY.

A new steam hoist has been installed at the Long Mary mine.—Operations have been resumed by lessees at the French Camp mine.—John Hanna, C. P. Pratt, and J. W. Pratt, have secured a lease on the Buckeye mine, and commenced operations at the property.

NEVADA COUNTY.

A. P. Wilson, the superintendent of the Prudential mine, near Grass Valley, is authority for the statement that the company will sink the shaft an additional 200 ft. on account of the discovery made at the mine a short time ago. A new cable will be purchased and sinking resumed before the first of December.—A new compressor and gasoline engine has been ordered for the Grover-Murphy mine, in the Nevada City district, and sinking will be resumed at the 250-ft. level. A cross-cut will also be started from this point to open the ore, which is thought to be the extension of the Mountaineer vein. Harry B. Gray is manager.—The raise from the south drift on the 900-ft. level of the Oustomah mine, opened a 10-in. vein of high-grade ore. Considerable free gold is present as well as zinc and galena. The raise is under the old Eddy workings, and is in unprospected ground. Frank M. Evans is superintendent.

SACRAMENTO COUNTY.

The committee appointed last July to investigate the condition of dredge mining on the American, Yuba, and Feather rivers, reported as follows: In regard to the actual dredge operations we find: 1. That the dredge operations on the American river are being conducted on lines and in such a manner that no injury to that stream is resulting therefrom. 2. That we commend the work of the dredges operating on the Yuba river under the direction of the California Débris Commission as the proper manner of dredging California streams, in that the tailing is removed from the flood action of the river, and the river itself is confined to its proper width, thereby securing the current necessary to insure proper depth of stream and the impounding of untold quantities of hydraulic tailing that would eventually find its way to the Feather and Sacramento rivers. 3. That the dredge operations on the Feather river, below Oroville, have been without system or organization; that the present operations are tending to greatly increase the flood plane of the river and great damage has resulted to the stream and the country adjacent thereto; and we recommend that the California Débris Commission assume control of the operations on this river, and institute a policy of rectification that will have for its object the improvement of the river, the lowering of the flood plane, and the control of its flood waters.

SHASTA COUNTY.

At the last meeting of the Shasta County Farmers' Protective Association, the executive committee recommended that Judge Marshall's modified decree be made the basis of an agreement in the settlement of the smoke question between the association and the smelting companies. In order to make the agreement binding for all parties it will be necessary to have a court decision, so a friendly suit will be brought, the details of which will be arranged between the lawyers of both parties.—George A. Von Kruse, the superintendent of the Sibil mine, in French gulch, has refused to turn over the Sibil claim to Charles O. Rose, trustee for the bondholders, who purchased the property recently at a court sale, on the ground that the assessment work was not performed and the claim located by his associates.

SIERRA COUNTY.

Some excellent gravel is being opened on the claims of Wendell Kallenberger, on Wolf creek, below the Plumbago mine.—The Sierra Porman, Bixby Consolidated, and Kate Hardy mines have been shut down for the winter on account of the recent heavy snow.—Frye & Winrod have brought 1600 lb. of rich concentrate from their property in Sailor ravine to Downieville, and are preparing to ship it to the Selby smelter.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A streak of ore 6 in. wide was cut last week in the breast of the Rochester adit on the Bellevue vein that assays 1030 oz. silver and 1.50 oz. gold per ton.—In prospecting an old stope on the Key West property, Leavenworth mountain, E. J. Butts discovered a streak of ore that is 8 in. wide, and assays 42% zinc, 15 oz. silver, and 0.10 oz. gold per ton.—The chemical laboratory at the new chemical-electro plant has been completed and the equipment is now being placed in position. S. Iodenes, the chemist, will start sampling ore in a few days.—A streak of ore 6 in. wide has just been cut by the raise from the Victoria adit level on the Frostberg vein that assays 320 oz. silver per ton and 40% lead. B. J. Martelon, of Denver, is manager.—During the last ten days the water in the Seven-Thirty shaft has been lowered over 70 ft. Owing to the pressure from above the drill-holes are becoming larger, and at the rate water is flowing the entire seven miles of underground workings will be drained inside 30 days.—A shipment of iron concentrate made last week from the Capital mines brought a settlement of \$34 per ton of gold. This is an increase of \$20 over that previously received.

Georgetown, November 19.

(Special Correspondence).—The Burns-Moore adit has intersected another vein at a distance of 4000 ft. from the portal. The heading of this bore is just penetrating the rich section of Chicago mountain, and within the next 1000 ft. a number of former heavy producing mines will be intersected at depth. W. W. Cannady is manager.—At the Lamartine mine a force of 20 men is being employed in the various leases and heavy shipments are being maintained. All work is being carried forward through the main adit level. The concentrating plant which has been handling dump-matter during the summer, has been closed owing to the lack of water. John Lang is manager.—At the Earl Kent mine, at Dumont, owned by W. P. Alkire, there is exposed in the adit an orebody that is from two to three feet wide that assays \$16 per ton.—O. Jaensen has been awarded a contract to drive the Adduddel lateral from the Newhouse tunnel a distance of 500 ft. This work is being performed by the Druid Mining Co., and is destined eventually to connect with the shaft of the Hazelton mine, where sinking has been in progress for several months past.—During the month of October the Newhouse tunnel was driven 215 ft. A strong water-course was cut during the month and as a result the flow from the tunnel has been almost doubled. A short distance from the present breast large switch and side-track accommodations have been blasted out. The owners of the Gardener property which was recently intersected, have called for bids for the driving of a lateral upon that vein.

Idaho Springs, November 20.

GILPIN COUNTY.

(Special Correspondence).—Lowe & Harris, operating the Rockford property in the Russell district, have awarded a contract to Hugh Williams for the sinking of the shaft 100 ft. The contract also provides for 100 ft. of driving. A new building and steam plant has just been placed in position. The shaft is now down 140 ft., ore having been produced from surface.—The shaft at the German mine has been cleaned and re-timbered to a depth of 300 ft. Drifts have been started on the 120-ft. level. R. Miller is in charge.—The 150-ft. shaft at the Gomer mine in the Russell district is to be sunk another 100 ft. A. A. Johnson, of Denver, is manager.—R. I. Hughes, of Russell gulch, who recently obtained a bond and lease on the Hughes mine on Bellevue mountain, has put work under way and at an early date shipments of both smelting and concentrating ore will be started.—Work has been resumed at the Argo mine, in Russell gulch, by the Argo Leasing Co. Harry Willis is manager.—A 6-in. streak of 4-oz. gold-bearing ore has been opened in the east 150 and 250-ft. levels of the Champion mine, in the Phoenix district. George Ross is manager.—The Polar Star mill, at Black Hawk, has been undergoing repairs during the last week.

This is a custom plant and a number of operators are sending heavy shipments. Theodore Nelson is operator.—A force of men is being employed in cleaning up around the pyritic smelter at Golden, preparatory to blowing-in the furnaces.—A streak of \$100 ore from 6 to 18 in. wide has been opened in the Gold Collar mine in a new stope that has been started above the 300-ft. level. Alfred Skeels is manager.

Central City, November 20.

LAKE COUNTY.

George F. Champion and associates have made arrangements for the resumption of work in the Little Bob mine and a portion of the workings of the Fanny Rawlings property in the Leadville district. A cross-cut will be started on the 350-ft. level and driven west through the Fanny Rawlings ground to open the orebody found in the St. Louis adit.—The Yak tunnel has cut a water course that is now draining the Resurrection No. 2 shaft, and it is expected that the workings will be free of water in a few weeks. A raise will be started to connect with the shaft as soon as the water is lowered. Considerable prospecting is being done on the Adelaide and Belgian-Frenchman claims through the tunnel.—The Saguache adit, west of Leadville, is now in over 500 ft. and the company is planning to install electrical equipment.—A portion of the Big Six ground is being worked through one of the Penn shafts. A 450-ft. drift has been run on the 600-ft. level opening several seams of high-grade ore.

OURAY COUNTY.

John Keleher, operating a lease on the shaft-workings of the El Mahdi mine, north of Ouray, has opened several streaks of silver ore. Two additional leases have been let on the property and considerable prospecting is being carried on.—A contract has been let to sink the shaft of the Congress mine, at Red Mountain, an additional 200 ft. This is now down 300 ft. and the contract calls for cross-cuts being driven to the vein on the 400 and 500-ft. levels.—John Gianino, operating the Mountain Lion mine, near Ironton under lease, shipped a car of ore from the property last week.

SAN JUAN COUNTY.

A body of ore assaying \$20 across the face has been found in the Champion mine at Silverton. A deep adit was driven to open the mine at depth, and when in 1950 ft. cut a 4-ft. vein. Drifts were started in both directions on this, and when in 75 ft., the south drift opened the ore which contains gold, silver, and lead, with a small percentage of copper.—John S. Fox has purchased the interest of John W. Essley, his partner, in the Alhambra group, near Animas Forks, and will thoroughly prospect the property.

SUMMIT COUNTY.

Twenty cars of ore were shipped from the Wellington mine recently and it is understood that the output is to be increased.—The Country Boy shipped 11 cars of zinc ore during the past month.—The management is shipping one car of ore per day from the Sallie Barber mine, in the Breckenridge district. Ten cars of high-grade zinc ore were forwarded to the smelter recently.

TELLER COUNTY.

Owing to a fall of rock in the Cookerly sublease on the Prince Albert ground, the output was cut down to one car per day of ore assaying \$12 per ton. The Union Leasing Co., holding the original lease on the property, has resumed work in the main adit and is driving east to open the Cookerly and Wilhelm shoots.—Three prospecting permits have been granted on the Kalamazoo and Little Joe claims of the Alert Gold Mining Co.—The Alabama Gold Mining & Leasing Co. was incorporated in Cripple Creek to operate a lease on the property of the Ajax Gold Mining Co., on Battle mountain.—Bunch & McNamee, operating a lease on the Burns mine of the Acacia Gold Mining Co., have opened a shoot of ore on the fourth level that assays between \$15 and \$30 per ton, and are shipping six cars per month.—J. E. Jones and associates, leasing the old C. O. D. mine in Poverty gulch, recently made a shipment of ore mined near the collar of the

incline shaft that assayed about \$25 per ton. Considerable prospecting work is being done in the mine and shipments will be made regularly in the future.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—The Caledonia Mining Co. is shipping 300 tons per month of lead-silver-copper ore from its group of six claims near Wardner. The mine is opened by a 500-ft. incline shaft in the quartzite foot-wall, with drifts on the vein from the 300 and 500-ft. stations. The vein is from 7 to 50 ft. wide. The first-grade ore contains from 30 to 60% lead, 2 oz. silver to each unit of lead, and 3 to 6% copper. The net return on one car of 30 tons was \$5000, and the shipments are incidental to development. Electric power is used in hoisting, and drilling is done by hand, but an air-compressor for power-drills is to be installed soon. There are about 45 men on the pay-roll. Charles McKinnis is manager for the company.—The National Copper Mining Co. has claims one mile west from the Snowstorm, near Mullan, containing a well defined vein, to open which a 4500-ft. cross-cut is being driven that will give 1700-ft. depth on the vein.—The Lucky Calumet joins the National on the east, and a long cross-cut being driven to its ore zone will give similar depth. This property is in charge of John H. Nordquist of Wallace.—The Ivanhoe company is driving from the Star workings to open the ore on its own property. These two lie west from the Morning mine.—The Snowshoe, which adjoins the Snowstorm, is under lease to George Houston and associates.—A contract has been let by B. M. Francis, of the Rex, on Nine Mile, for 500 ft. of sinking. The Rex has the requisite equipment for this work.

Wardner, November 20.

MONTANA.

SILVER BOW COUNTY.

(Special Correspondence).—The Butte-Ballaklava is raising the third compartment of its shaft from the 500-ft. level to the surface, and mining on the 300, making regular shipments of ore. A new steel head-frame is also being erected. The orebodies are sufficiently opened for a production of fully 10,000,000 lb. of copper per year.—The Butte Coalition company, whose stock has had a period of activity recently for the first time in several years, is gradually increasing its production and is now mining about 2000 tons of ore per day, and is producing copper at the rate of about 45,000,000 lb. per year.—F. A. Heinze has begun repairs at the Basin concentrator, owned by La France Copper company, and it is understood that Davis-Daly ore from the Colorado mine will be handled there.—Robert H. Gross and James H. Reed have completed their examination of the properties and affairs of the East Butte Copper Mining Co., and both are very well satisfied. Before leaving for Boston Mr. Gross said the East Butte was now the largest independent copper producing company operating in the Butte district, its production at present being in excess of 7,000,000 lb. per year.—There is another mystery working in the British-Butte Mining Co. The big dredge, which has been working on some placer beds a few miles west of Butte, has again been shut down, and the company is at present without a local manager. Manuel H. De Hora had been manager for the company up to a few months ago, when he was called to London. Upon his arrival there a cablegram came to Butte stating that he had resigned and would not return. Norman Jenks, son of one of the London stockholders of the company, remained as manager for a month, and then word came that Mr. De Hora was on his way to Butte, whereupon Mr. Jenks shut down the dredge, and hastily started for London. Before his departure, Mr. Jenks had let a contract for development and exploration work by means of drills, which seems to indicate anything but a satisfactory condition.

Butte, November 20.

NEVADA.

CLARK COUNTY.

The winze on the 170-ft. level of the New Year's Gift lease, at Searchlight, opened 2½ ft. of \$40 ore when down

26 ft. The shaft will be sunk to the 250-ft. level, a cross-cut run to the vein, and a drift driven to connect with the winze.—Cook, Chase & Zook, shipped 100 tons of ore from the I. X. L. lease to the Cyrus Noble mill, although a contract had been made with E. J. Knight, who is erecting a custom plant. A blacksmith shop and ore-bins have been erected near the portal of the adit.—There are 40 sacks of ore on the dump at the Morel lease, on the Good Hope property, that assays from \$23 to \$73 per ton. The ore occurs in small stringers and the ground is pockety. E. E. Perkins is in charge of the work.—Sinking has been resumed at the 300-ft. level of the Lenape property and it is the intention of the company to continue to the 1000-ft. point.—The White Rock Mining Co., operating 25 miles southeast of Searchlight, has built a wagon-road to the property and installed a 50-hp. engine, compressor, and machine-drills. A new adit has been started that will cut the vein at a depth of 100 feet.

ESMERALDA COUNTY.

Philadelphia operators who are sinking the old Goldfield Annex shaft on the Poleverde claim has found a strong vein at the 600-ft. level that is believed to be the extension of the Clermont. The work is but a short distance from the Consolidated's Clermont shaft, and the vein will be explored at this depth while the shaft is continued to 1000 ft.—At the 625-ft. level the shaft of the Precious Metals Co.'s lease on the Atlanta is in vein matter. It is thought to be the St. Ives vein, from which high-grade ore has been taken on the adjoining claims.—Driving is in progress from the shaft of the Fairview Cherokee lease on the Atlanta at the 640-ft. level, where the vein was opened from which good assays were secured above the 500-ft. level.—A favorable showing is being made on the Velvet claim of the Merger Mines Co., where William MacKay and associates are working both the company shaft and the St. Ives.—Work has been resumed on the old Chicago Florence, originally a sub-lease from the Rogers Syndicate lease, south of the Florence hill. The 425-ft. shaft will be sunk to the 600-ft. level, and from this point the territory formerly embraced in the Gatzert lease will be prospected.—The plant of the Little Florence Leasing Co. has been sold to the Buckeye-Tonopah Co. This plant, including a powerful compressor and costing about \$12,000, was installed by the leasing company only a month before its operations were suspended and its lease on the Fraction forfeited.—A 200-ton gyratory crusher has been installed in the Florence mill and the plant is now treating 160 tons per day. A spur has been extended from the Tonopah & Tidewater railroad to the mill.—The Thomas lease at Columbian mountain is down 140 ft. with a foot of shipping ore and 18 in. milling in an 8-ft. vein.

HUMBOLDT COUNTY.

The 70-ft. shaft of the Washakie mine, 26 miles south of Winnemucca, opened a body of high-grade ore and the company is planning the erection of a small mill.—The Seven Troughs Monarch Mining Co. is to resume operations shortly.—The Buckhorn and Florence lessees have found good ore in their blocks.

NYE COUNTY.

Two feet of \$50 ore has been opened on the claims of the Nevada National Mining Co., in Paulsen canyon. The main development on the property is the shaft, though the vein has been opened in several places by surface trenching. Nels Paulsen is superintendent.—The management of the Round Mountain Mining Co. is considering the use of a steam shovel at its property on the southern slope of the mountain. Should the company adopt this method, the capacity of the Sunnyside mill will be greatly increased. There are a number of properties in that district where the ground contains rich stringers that could be profitably handled on a large scale.

WHITE PINE COUNTY

The output from the Copper Flat group of the Nevada Consolidated is being kept up to the record work of last month and it is probable that the November tonnage will equal that of October. The main office of the Consolidated company has been moved to the eastern side of the Flat to

be nearer the work.—The 5-compartment shaft on the Alpha claim of the Giroux property is down four sets which have been re-inforced with concrete. The raise which was started from the 1000-ft. level to connect with the shaft is now within 320 ft. of the bottom of the shaft. The foundations for the machinery have been set in place and a head-frame and surface buildings are being erected.—On the Ely Consolidated the company is cross-cutting on the 400-ft. level of the Brilliant shaft, and has opened some ore that assays \$6 gold per ton.—A large hoist and compressor have been purchased by the Ely Calumet company, and will be installed at the mine in a short time when a 500-ft. shaft will be started. On the eastern slope of the mountain an adit will be started that will cut the ore at a depth of 1100 feet.

OREGON.

BAKER COUNTY.

The adit at the Ophir mine, in the Baker City district, being run to open the ore 200 ft. below the present workings cut a blind vein that was 7 ft. wide.—At a meeting of the stockholders of the Humboldt Gold Mines Co., held in Baker City, the management reported that the mill of the company in Mormon basin was running night and day and good ore was being blocked out in the mine. John Arthur was elected manager.—The tube-mill which was recently installed at the Cougar mine is running successfully.

UTAH.

BOXELDER COUNTY.

The Homber Mining Co., which has been opening a deposit of graphite four miles south of Brigham City for the past few months, made its first shipment of one car to Salt Lake City. W. W. Cannon is in charge of the work.

JUAB COUNTY.

The East Tintic Development Co. is shipping five cars of ore per week that is netting the company about \$700 per car. The management expects to open the ore on the 500-ft. level in a short time.—The Mammoth company is employing about 40 men and is shipping two cars of ore per week. It is understood that the company is trying to obtain a better rate with the smelter and will increase the output if this is obtained.—A new pump has been installed and sinking resumed in the shaft at the Tintic Central.—At the Eagle and Blue Bell mine good ore is being opened on the 900, 1000, and 1100-ft. levels. New machinery is being installed at the mine and a small hoist will be placed at the 1000-ft. level while sinking to the 1200.—Some good ore has been opened in the old Scotia mine in West Tintic and shipping resumed.

SUMMIT COUNTY.

The adit at the property of the Thor Mining Co., in the Park City district, is now in 200 ft. and has cut several stringers of ore. A shaft was started on the property but was abandoned on account of a heavy flow of water. The group will be drained, however, by the tunnel the Daly-Judge company proposes to drive. Peter Cass is in charge of the work.—The shaft at the New York Bonanza property is down 970 ft. This will be continued and cross-cuts started on the 1000-ft. level about the first of the year.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Q. S. Mining Co., operating between Loomis and Conconully, is installing a hydro-electric power plant and an air-compressor and will use air-drills in driving a 2400-ft. cross-cut to the vein, which will give a depth on the latter of 2000 ft. The ore is said to assay $2\frac{1}{2}$ to $4\frac{1}{2}$ copper, with some gold and silver. A. M. Dewey, of Spokane, is manager.—J. T. Plant is erecting a reduction plant in Ruby canyon, five miles south of Conconully.

Loomis, November 20.

STEVENS COUNTY.

(Special Correspondence).—The Oriole mine, in Metairie district, is being equipped with a steam boiler, Sullivan air-compressor, and two drills, which are to be in operation in December. The incline shaft, now 60 ft. deep,

is to be sunk to a depth of 350 ft. The ore now exposed is said to assay \$45 per ton in lead, silver, and gold. The vein has well defined walls and is 6 ft. wide. An adit and other work aggregates 700 ft. Joseph Lancaster, of Spokane, is directing the work, and Fred N. Davis is manager. —The United Copper Co., Conrad Wolfe, manager, has spent about \$100,000 developing its copper property 4½ miles northeast of Chewelah. Incidental to development the company has shipped about 1000 tons of copper ore. The principal development is from a 450-ft. shaft, but work has commenced on a 3000-ft. adit which is to intersect the vein at 1100 ft. below the surface. This work has advanced 200 ft., and an air-compressor and drills are being installed. A force of 16 men is employed. —T. F. Hertzell, of Chewelah, controls the property of the High Grade Silver

Sheep Creek district, has been acquired by a local syndicate, which has made one payment on the property. Work has been started on the group. —The second payment has been made on the Golden Fawn, which adjoins the Searchlight group, by the Vancouver bondholders. Work has not been commenced on this property as yet, but a contract has been let to drive a cross-cut adit. —Sinking of the main shaft on the Highland-Buckeye property has resulted in the discovery of a 4-ft. lead of good ore. The company shipped 26 tons of ore to Trail smelter in the early part of the month, but expects to increase its shipments materially as soon as the air-compressor and machine-drills are installed.

—After 30 days' hard work the railway into Sandon has been re-built over the slides and ore shipments resumed. Several of the important mines are soon to resume work and things look brighter for Sandon than they have for some years. —In the Portland Canal mining district, which has come noticeably to the front this year, active development work is being pushed on the property of both the Portland Canal Mining Co. and that of the Stewart Mining Co. A 200-hp. steam air-compressor has been ordered for the Red Cliff property, which will be a heavy shipper next spring. Money is being raised to build a short railway for hauling the ore to the water front, a distance of five miles. —Within a radius of 100 miles of Hazelton on Skeena river, there are three rich and promising mining districts, the Telkwa, Babine, and Nine Mile mountain. Notable examples of the operations in this district during the past season were the development and bonding of the Harris group at Nine Mile for \$60,000; the appraisal of the Telkwa coal fields by a Pittsburgh expert, the executing of several hundred feet of development work on the St. Eugene group, Babine, and the driving of a 400-ft. adit at the Dibble group, owned by James Cronin, one of the original owners of the St. Eugene at Moyle, the largest lead-silver mine in Canada. There is an excellent showing of silver-lead ore on the Dibble group. The country for miles around these two last named properties has been staked, and many promising veins of copper and silver ore uncovered.

Rossland, November 20.

MEXICO.

CHIHUAHUA.

The Dolores Mines Co. recently shipped two lots of high-grade ore from its Dolores mine 45 miles west of Madera to the El Paso smelter. The first lot of 25 tons assayed 16 oz. gold and 900 oz. silver per ton, and the second lot of zinc shorts assayed 18 oz. gold and 5000 oz. silver per ton. W. H. Paul is manager. —The grading for the spur to the New Palmilla mill at Parral has been completed and the rails will be laid in a short time. The cement for the concrete has arrived and the foundations are being constructed. —It is understood that the management of the Sta. Rosalia smelter is to double the present capacity of the plant to handle 500 tons of ore per day.

JALISCO.

The Dwight Furness company has just purchased 36 tons of high-grade gold-copper-silver ore from Edward Fitzpatrick at Ameca, the sale netting Mr. Fitzpatrick over \$200 per ton. —A cross-cut from the shaft under the old workings in the Boca Ancha mine, in the Ayutla district, opened a body of rich ore and the management is planning for the erection of a concentrator. —Charles Whittemore has organized a company which is backed by London and Paris capitalists to build a railroad from Chamela on the Pacific Coast to La Vega on the National lines. It is understood that over £1,000,000 has been subscribed for the enterprise. The line will be standard gauge and 325 kilometers long.

EAST SIBERIA.

At the Kolchan mines, despite a short season and low water, the clean-up is \$45,000 from approximately 35,000 cubic yards.

Portland Canal District.

& Copper Co., three miles from the town. He has opened a vein of high-grade copper, silver, and lead ore on the contact of slate and porphyry. A steam hoist and pump have been installed. —The Blue Star group, of seven claims, near that of the United Copper Co. has series of veins in lime and quartzite, containing silver, lead, copper, and gold. Mark Mitchell, of Chewelah, who operates the property, has a small force at work, and states that the percentage of copper increases with depth. —About \$100,000 worth of ore was shipped from the mine by previous operators, some of it assaying as high as \$60 per ton.

Chewelah, November 20.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence). —The Searchlight group of three claims near the Mother Lode and Nugget claims,

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. S. NOYES has gone to Oregon.
 W. E. THORNE is in San Francisco.
 HOWARD D. SMITH has gone to Spain.
 GEORGE H. GARREY is at Mapimi, Mexico.
 REEVES DAVIS was in Stockton this week.
 VICTOR F. G. SEAWELL is in San Francisco.
 WALTER HARVEY WEED is at Phoenix, Arizona.
 N. SAMWELL has gone to Milwaukee, Wisconsin.
 A. O. ZINN, of Manila, has been in San Francisco.
 J. E. SPURR has gone to Salt Lake from Portland.
 H. A. DENNY has returned from London to Mexico.
 GODFREY D. DOVETON is at the Santa Gertrúdis, Pachuca.
 W. H. CRAWFORD has returned to Boston from New York.
 C. S. HERZIG has returned to New York from Ray, Arizona.
 CLAUDE E. JAMISON, of Los Angeles, was in San Francisco.
 M. E. MACDONALD has just returned to New York from Cobalt.
 A. F. HUGHES has gone to the Rio Plata mine, Chihuahua, Mexico.
 RICHARD KLEESATTEL, of Seattle, Washington, has gone to National, Nevada.
 H. A. TITCOMB is at Salt Lake in connection with the Silver King litigation.
 J. R. FINLAY has been appointed general manager for the Goldfield Consolidated.
 WALTER G. PERKINS is in London and expects shortly to return to San Francisco.
 C. H. MUNRO has reached San Francisco from Nome and will spend the winter here.
 FRANK H. PROBERT is at Globe, Arizona, inspecting the Superior & Boston copper mines.
 F. W. DEWOLF and W. H. HERBON have returned to Urbana, Illinois, from New Orleans.
 J. H. MACKENZIE has resigned the position of general manager for the Goldfield Consolidated.
 E. H. MACDONALD, of Butte, Montana, has been making geological investigations at Chewelah, Washington.
 S. F. EMMONS recently received the honorary degree of Doctor of Science from his *alma mater*, Harvard University.
 VICTOR RAKOWSKY has completed an examination of zinc-lead properties in Oklahoma and has returned to Duluth, Minnesota.
 FREDERIC KEEFER, consulting engineer for the B. C. Copper Co., recently examined properties on Sheep creek, near Ymir, British Columbia.
 W. G. ANDERSON, recently with the El Favor Mining Co., Hostotipaquillo, Jalisco, Mexico, is now with the Compañía Minera La Republica, S. A., Sauz Dto. Rayon, Chihuahua, Mexico.

NICKEL used in the United States comes almost wholly from the deposits at Sudbury, Ontario, the domestic production being too small to be of much importance. In 1908 the imports for consumption had a total value of \$2,497,585; in 1907 the value was \$2,243,026. The United States refines much more nickel than it can use, so that, though not a producer, it is a large exporter. The exports in 1908 were 9,770,248 lb., valued at \$3,297,988, against 8,772,578 lb., valued at \$2,845,663, in 1907. Large quantities of cobalt minerals are contained in the silver ores at Cobalt, Ontario, and the greater part of the cobalt used in the United States comes from this locality. The imports for consumption in 1908 were 219,098 lb., valued at \$17,077.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

GYPSUM A MINERAL.

Gypsum is a mineral and lands containing it are mineral lands within the meaning of the United States Statutes providing for the location of mines and their relation to mineral lands.

Madison v. Octave Oil Co., (Cal.) 99 Pac. 176, Dec. '08.

LEASE OF MINES—FORFEITURE.

Where the owner of lands leased the mineral rights therein to another, on condition that if the property remain idle for 30 successive days, the lease should be void, the condition being broken, the lessor had a right to treat the lease as null and void, and sue and recover possession.

Trumbo v. Persons, (Ky.) 118 Southwest. 916, Apr. '09.

OIL LEASE—RECISSION.

The purchaser of an oil lease is not prevented from maintaining an action for the recission thereof on the ground of fraud, for the reason that he had used up a part of the oil which he had received from the property, because of his inability to place the purchaser in statu quo. While he had rendered impossible the restoration in specie of all that he had received in the transaction, it was sufficient in such case if he restored or offered to restore its money equivalent; and this is the rule where the property received is used or lost so that it cannot be restored in specie, when its value is capable of being ascertained.

Bayse v. Paola Ref. Co., (Kan.) 101 Pac. 658, Apr. '09.

LOCATION OF MINE—FAILURE TO PERFORM ASSESSMENT WORK—FORFEITURE.

The United States Statutes provide that on failure by the locator of a mining claim to perform the required assessment work, the claim shall be open to re-location, provided the original locator has not resumed work on the claim after such failure and before a re-location is made. Under this statute it has been decided in California that a mere failure to comply with the requirements as to the performance of the assessment work did not terminate the right of the locator; that the only effect of such failure was to throw the land open to location by others; and in the absence of any other location, the original claimant had the right to resume work and hold his claim. And this right and his estate is not divested until there has been a peaceable entry for the purpose of re-location by another person.

Madison v. Octave Oil Co., (Cal.) 99 Pac. 176, Dec. '08.

FLOODING MINE—DAMAGES.

A corporation drilling a well on its own land, but near a mine, drilled through sandstone into a shale that lies above the slate which served as a roof immediately over the coal in the plaintiff's mine, and the loose shale permitted the water to pass through it down to the slate and to weaken the strength of the covering of the mine so that it fell and caused the mine to be flooded. It was charged that the company drilling the well knew the subterranean formations in that locality, and that if it drilled the well as it did, injuries would result to the mine. It was also charged that after the well had been drilled and the water began to flow from it into the mine the company made no effort to prevent it. In an action for damages, the court left it to the jury under proper instructions to determine whether the defendant in drilling the well should have had such knowledge of the character of the strata as would lead it to believe that the water might flow from the well into the mine; and that if such was the character of the strata, and the fact was of common notoriety, the company would be chargeable with such knowledge and under the instructions and the facts, a judgment for the plaintiff for the damages was sustained.

Muntz v. Cottage Hill Land Co., (Pa.) 72 Atl. 247, Jan. '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

DEVONIAN FAUNA OF THE OURAY LIMESTONE. By E. M. Kindle, U. S. Geol. Surv., Bull. 391, Pp. 60. Ill. Washington, 1909.

LANDSLIDES IN THE SAN JUAN, COLORADO. By Ernest Hoge. U. S. Geol. Surv., Prof. Paper, 67. Pp. 58, ill. Washington, 1909.

PRODUCTION OF CHROMITE IN CANADA. Department of Mines. Pamphlet, 6 pages. Ottawa, 1909. Figures for the year 1907-8.

SPIRIT LEVELING IN WEST VIRGINIA, 1896 TO 1908. Compiled by S. S. Gannett and D. H. Baldwin. U. S. Geol. Surv., Bull. 399. Pp. 81. Washington, 1909.

PRODUCTION OF ASBESTOS IN CANADA. Department of Mines. Pamphlet, 8 pages. Ottawa, 1909. Figures of production for 1907-8 are given.

INVESTIGATIONS RELATING TO PETROLEUM AND NATURAL GAS IN 1908. By Robert Anderson, D. T. Day, J. A. Taff, W. J. Reed, and C. W. Washburne. U. S. Geol. Surv., Bull. 381-D. Washington, 1909.

METALLOGRAFIA. By Umberto Savoia. 4 by 6, pp. 205, 94 fig. Milano, 1909. Published by Ulrico Hoepli. Price \$1. A historical sketch of the science, description of methods of preparation of microscopic sections, and a general account of the metallography of iron and steel.

MINERAL RESOURCES OF THE UNITED STATES FOR 1908. U. S. Geol. Surv., Washington, 1909.

Advance separates as follows have been received: Production of Antimony, Arsenic, Bismuth, Selenium, and Tellurium, by F. L. Hess; Iron Ores, Pig Iron, and Steel, by E. C. Harder; Glass Sand, Other Sand, and Gravel, by E. F. Burchard.

YAKUTAT BAY REGION, ALASKA. By R. S. Tarr and B. S. Butler. U. S. Geol. Surv., Prof. Paper, 64. Pp. 183, ill. Washington, 1909.

This report includes accounts of the physiography and glacial geology by Mr. Tarr, and of the areal geology by Mr. Tarr and Mr. Butler. It is accompanied by an excellent map.

METALLURGY OF THE COMMON METALS. By L. S. Austin. Second edition, rewritten and enlarged. 6 by 9. Pp. 494. Fig. 195. Index. MINING AND SCIENTIFIC PRESS, San Francisco, 1909. Price \$4.

Metallurgy is a broad subject, and to describe a large part of it in a single volume seems impossible. Gold, silver, iron, copper, lead, and zinc, are well described by Mr. Austin, however, in his second edition. There are many processes of treating the ores of these metals, and many of them are new or are much improved, but all the things that are most important are found in this book. We do not expect to find everything known compressed into one volume, nor do we want all that has ever been written, collected into one great work. The matter would be too voluminous to be of any use. But when someone that knows gives us the principles, arranged and ready to use, out from the confusion of it all, we are glad to get them. Mr. Austin has done this by eliminating unimportant things and exposing the real thing for us to see. The illustrations are good, and the five hundred pages of description present the subject clearly. It would be an exceptional man who could read the book without profit, and a dull one that could not understand it. For a beginner it is safe and is built squarely upon conventional lines. For the expert it is alive with modern American conditions and best practice. For the man that has begun to realize that he must have in his library the knowledge that he cannot hope to keep uppermost in mind, it is a book important to have.—K. F. D.

COMPANY REPORTS.

BROKEN HILL SOUTH SILVER MINING COMPANY.

The properties of this company, though situated at Broken Hill, New South Wales, were not involved in the labor troubles of the last year. Accordingly the report for the half year ending June 30, shows £40,000 paid in dividends, £10,416 written off for depreciation, and a balance credit of £120,638 carried forward, with £58,902 net liquid assets. A contract has been made with the De Bavay's Treatment Co. for treatment of zinc tailing on joint account for seven years, with a possible extension of three years. The terms involve an advance of 3s. 6d. per ton as delivered. After a similar amount has been credited to the treatment company, actual costs are to be figured and the balance divided. This contract is to go into force January 1. In the meantime the tailing is being sold to the De Bavay company at a flat rate of 3s. 6d. The ore hoisted in the half year amounted to 112,288 tons, assaying 16.2% Pb, 5.6 oz. Ag, and 12.1% Zn. Of this, 68% came from the 825 and 970-ft. levels of the mine. This ore was produced with an average daily attendance of 261 surface men and 540 underground. The ore reserves are estimated by W. E. Wainwright, manager, at 3,250,000 tons, to which may be added the following products on hand: old mill tailing, 1,078,743 tons, assaying 3.7 oz. Ag, 6% Pb, and 16.7 Zn; new mill zinc tailing, 74,602 tons, assaying 3.4 oz. Ag, 4.1% Pb, 18.7 Zn; old mill slime, 140,432 tons, assaying 6 oz. Ag, 14.7% Pb, 16.7 Zn; new mill slime, 35,366, assaying, 5.8 oz. Ag, 13.4% Pb, 12.1 Zn. The cost for the period amounted to 13s. 10.6d. per ton of crude ore, divided into 9s. 2.5d. for mining, 9s. 11.6d. for development, 3s. 11d. for concentrating. This is equivalent to £4 12s. 3.1d. per ton of concentrate. The report includes a large amount of other data of interest to technical men, and particularly to American zinc producers.

BULLION MINING CO., LTD.

This company owns a copper property in the Coeur d'Alene district. The report of the manager under date of October 1 shows that 1899 ft. of development has been accomplished, and J. P. Rowe is authority for the statement that the vein is nearly vertical, is 4 to 15 ft. wide, and that two ore-shoots have been discovered. The company is capitalized at \$1,500,000, with 361,812 shares of a par value of \$1 each, still in the treasury. The expenditure to date has amounted to \$46,820, less \$1384 cash on hand. This money was realized by treasury stock sales to the amount of \$30,739, assessments, \$15,364, and advances, \$717. The property is evidently some distance from profitable production. The contrast between capitalization and actual expenditures is startling, but characteristic of the optimistic attitude of promoters. The auditors' report in this case is detailed and full. The account of the property itself is less satisfactory.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to September, 1909:

| | Tons. |
|------------------------|---------|
| Imports of copper..... | 120,927 |
| Exports of copper..... | 5,967 |

Consumption of copper..... 114,960

Consumption during the same period in 1908 was 116,162 tons. Of the above quantity 110,840 tons were imported from the United States.

ANTIMONY was not largely produced in the United States in 1908, according to the Geological Survey. Only one lot of ore whose value was chiefly confined to its content of antimony was mined and marketed—a lot mined near Mill City, Nevada. Most of the antimony sold in this country is contained in antimonial lead, from which the lead is not separated in its common uses. Antimony, unlike most other metals, does not shrink in volume on cooling after it has been melted; on the contrary, it expands, and for this reason it is used, generally in the form of antimonial lead combined with other metals, in making printer's type and other castings requiring sharp faces or outlines.

Commercial Paragraphs.

The PACIFIC FOUNDRY Co., of San Francisco, California, announces the sale of three Kilker's matte tapping cars to the Modern Smelting & Refining Co., Utah Junction, Denver, Colorado.

The Hardinge conical mill is being tested by the Johannesburg Mines Investigation committee. This mill is to handle the ores shipped for testing by many of the largest mines in South Africa.

W. L. COOPER, manager of ROBERT W. HUNT & Co.'s European business, sailed from New York on November 10, returning to London after the completion of his annual business trip to the United States.

The Jackson hand-power rock-drill was awarded a gold medal at the Alaska-Yukon-Pacific Exposition. The award covers efficiency and ease of operation. This drill is made and sold by THE MINING SUPPLY Co., New York.

The services of C. E. ALLEN have just been secured by the WESTINGHOUSE ELECTRIC & MFG. Co. in connection with the sales of transformers. Mr. Allen was formerly connected with the General Electric Co. in a similar capacity, but resigned from that company during the past summer.

THE FOOS GAS ENGINE Co., Springfield, Ohio, announces the receipt of an order for six 150-hp. three-cylinder Foos vertical engines from the Hazel-Atlas Glass Co., Wheeling, West Virginia. The latter company has been using a number of these same engines during the last eight years, and hence the order is an indication of the satisfaction Foos engines are giving for power-plant service. The engine company advises that its factory is running at full capacity, employing two shifts, and still is unable to keep up with orders.

THE C. O. BARTLETT & SNOW Co. announces the following recent sales: Crow's Nest Pass Coal Co., Fernie, British Columbia, additional coal-handling machinery; Maryland Steel Co., Steelton, Pennsylvania, conveyors and elevators; National Refining Co., Findlay, Ohio, conveyors and elevators; National Tube Co., Pittsburg, Pennsylvania, conveyors and elevators; Winding Gulf Colliery Co., Cincinnati, Ohio, complete coal tipples and Greene Self-Dumping Car Haul, through F. C. Greene, engineer; United States Smelting, Refining & Mining Co., Salt Lake City, Utah, ore dryer.

A Large Blast.

An unusually large amount of rock, 120,000 cu. yd., was recently brought down by a single blast at Morena, California, in connection with the construction of a dam for the Southern California Water Co. An adit 125 ft. long was driven straight into the face of the hard granite rock to be blasted. The mouth was at the foot of the sloping rock, over the face was a burden of 140 ft. Two short side drifts from the main adit had been driven, in which had been placed 33,550 lb. of Champion powder, 2000 lb. of 60% dynamite, and 3400 lb. of 40% dynamite, 38,950 lb. in all. Three 20-ft. double-strength electric fuses, connected in series, were used, the fuses being buried in the loose powder and brought out along the west wall of the tunnel. The side drifts and main adit were well tamped with fine dirt. The main adit was filled with earth and rock tamping to within 20 ft. of the adit mouth. Five hundred feet of double-lead wire connected the tunnel wiring and the battery. During the loading the men were required to surrender matches and smoking materials, and their feet, from which their shoes had been removed, were covered with sacking. The circuit was tested frequently during tamping, that possible breaks might be detected and repaired before burying the wires too deeply.

ARSENIC during 1908 was produced in a commercial way at only two places in the United States—by the American Smelters Securities Co., at its plant at Everett, Washington, and by the Washoe Copper Co., at the Washoe smelter, Anaconda, Montana, according to the United States Geological Survey. The product was in the form of white arsenic (arsenic trioxide) and was derived largely from flue-dust.

EDITORIAL.

WESTERN headquarters for the Cole-Ryan interests are to be established at Salt Lake, to facilitate the handling of details regarding mining in Nevada and Utah especially. Their Butte mines and all general financial policies will continue to be directed from New York.

THOSE who are familiar with the recent litigation between the Calumet & Hecla Mining Company and Mr. A. S. Bigelow over the Osceola stock, will understand that a consolidation of that corporation with other copper producers would be impossible. By the laws of Michigan such an act would operate forfeiture of charter. In this, combined with the low cost of its copper, are found sufficient reasons for the lofty isolation of the great Michigan copper company.

THE sixty-first meeting of the American Association for the Advancement of Science, will be held in Boston, December 27 to January 1. At the same time the usual meetings of the affiliated societies, now grown to number twenty-seven, will be in session. The A²S, as the association is frequently called, is a large and important organization. It serves a most useful purpose in bringing together once a year, the leaders in the various branches of science. This year Mr. David Starr Jordan will be the presiding officer.

THE MAGNITUDE of the interests of the Consolidated Gold Fields of South Africa is instanced in the fact that for the year ended August 31, its subsidiary companies, the Simmer & Jack, Robinson Deep, Knights Deep, Simmer East, Jupiter, Simmer Deep, and Nigel Deep, produced 984,302 ounces of gold. These companies employ 1350 stamps of the 9842 dropping on the Rand, and 24 of the 144 tube-mills there in use. They crushed 3,224,168 of the 22,033,857 tons of ore handled, and made a total mining profit for the year of £1,658,966.

PROMOTERS' ways are many and devious and new means of booming stocks constantly are found. They stop at no means. Last April Mr. Waldemar Lindgren was quoted in *The Herald*, of Parker, Arizona, as praising in most extravagant fashion a property near that place. He promptly sent a denial of the statements attributed to him, but only in October was his letter printed. In the meantime stock in the company possessing this particular hole in the ground, was jumped from 15 cents to 50; a flattering recognition, at least, of the value of Mr. Lindgren's opinion. It was only after the stock was sold and the promoter had left the country that *The Herald* published Mr. Lindgren's denial. It now

affects a finely righteous indignation against the wiley promoter. The whole transaction is, unfortunately, typical of the ordinary attitude in a mining camp where 'boosters, not knockers, are wanted'—regardless too often of the truth.

RECIPROCITY with a club is a frequent feature of trade relations with Germany. It is now intimated that the Reichstag may impose an export tax on crude potash. This has been met by rumors from Washington, said to be 'inspired', that the clause of the Payne-Aldrich tariff bill providing for reprisals in case of unjust discrimination, may be applied to meet such action on the part of Germany. Since the latter country holds a monopoly upon potash it is not surprising that it should guard this exclusive asset jealously. It is well to remember that this spirit may be operative in the German mind as well as that of taking commercial advantage of the situation. In any case, it indicates the importance of continued efforts to discover deposits of potash in this country. America consumes half of the total exportation of German potash, the value of that product taken in 1908 exceeding \$5,000,000.

PETROLEUM lands to the extent of three million acres, lying in California, Wyoming, Utah, and Oregon, have been withdrawn from entry. This is a temporary measure to promote a proposed revision of the laws controlling the disposition of such lands. The anomaly of considering oil land as placer has long led to confusion and trouble. The insistence on actual discovery in order to perfect title, in this case works hardship, since in the nature of the case honest discovery can only be made by drilling, and this necessitates more rapid development than is usually wise if any considerable area is to be held. It would seem that oil lands afford a good field for a trial of the leasing system. It is the plan upon which most of the oil territory in the United States has been opened and is one with which all oil men are familiar. Its adoption would equalize conditions between different oil fields, would enable the Government to reserve as much oil as might seem necessary for naval uses, would promote economical rather than wasteful development, and would take full advantage of the slow growth of experience in oil development. The present situation demands prompt remedy.

Food and Mining in Mexico.

Trade between the Latin-American countries has been relatively unimportant up to the present, and has been due chiefly to natural attraction resulting from propinquity. A new departure is now to be made, however, which strikingly illustrates the growing commercial power of the southern republics. The industrial development of Mexico has been steadily reducing the production of grain in proportion to the consumption, so that corn-famines have become increasingly frequent. At the same time it has been observed that Argentina consumes large quantities of manufactures from heniquen, which is produced in Mexico and exported to the

extent of \$15,000,000 yearly to the United States. Arrangements are now being made with the Lloyd-Brasillero steamship line to establish regular steamship service between Mexican ports and Buenos Aires. It is said that orders for 300,000 tons of Argentine corn have been placed in Mexico as a basis for initiating such trade relations, and that rope and jute-sack factories will be established in Argentina to consume Mexican heniquen. These activities may be taken in a certain sense as a measure of the rapid growth of the Mexican mining industries which have drawn so large a proportion of the population from agricultural pursuits. The opening of the Southern Pacific of Mexico's line to Guadalajara will, of course, admit the products of the great agricultural regions of Sonora, Sinaloa, and Tepic to the central plateau markets. Cheap supplies will promote the mineral development of the country. Cheap food is an essential to the economic conduct of mining operations, and Mexican mines are constantly being embarrassed by a shortage of corn and beans. The Mexican Government has appointed a *junta* to purchase and distribute these necessities throughout the Republic. The Government will buy 200,000 hectolitres of corn, equivalent to 30,870,000 pounds, and bids for beans have been submitted from California, Austria, Spain, and other parts of the world. Some mining companies in Mexico have found it profitable to rent land under their control to natives, furnishing seed, and in other ways encouraging local production. This not only keeps down the local price, but serves to check the tendency of Mexican miners to quit work at the planting season to raise crops in the vicinity of their homes, a custom which causes great fluctuation in the available force at the mines. It is certainly the part of wisdom to facilitate food production in the vicinity of such properties. In the United States this matter regulates itself, but conditions in Mexico are different.

Pacification of Nicaragua.

Political changes are imminent in Nicaragua. These will mean much to American investors in the mines of that Republic. The reign of Zelaya is evidently near its end. Only a decisive victory over the revolutionists could now re-establish his power so that he would be able to compel Secretary Knox to disregard the threats contained in the letter accompanying the passports handed to Mr. Felipe Rodriguez, *Charge d'Affaires* for Nicaragua, on Wednesday last. The execution of Messrs. Cannon and Groce, American citizens, taken under arms in the service of the Nicaraguan insurgents, is there interpreted as a personal offense chargeable to the authority by whose order the execution was made. That means Zelaya! If unsuccessful in repressing the revolution, Zelaya would be condemned to death by his triumphant opponents, sure of the acquiescence of the American Government: if successful—what would Mr. Taft do to make good the threat of his Secretary of State? Would the United States assume the rôle of guardian, as it did toward Cuba? Would such a step, if taken, recognize the interest which neighbor nations have in regard to their independence, by engagements made with them to with-

draw upon restoring a stable government? This country can ill afford to arouse suspicion of its motives on the part of the Mexican people. A line must be drawn between the official co-operation of the Mexican Government in this Nicaraguan affair and the anxiety felt by the masses. Mutterings come from many quarters south of the Rio Grande, concerning undue influence by the United Fruit Company in the revolt against the Zelaya administration. That company failed to enjoy favor in the eyes of the potentate at Managua. There was also friction at Bluefields, the hatchery of the revolution, between Mr. Samuel Weil and Belanger's Incorporated, which is supposed to have had political bearings. American interests were evidently involved to such an extent in the beginnings of the uprising that we may well watch the end to see that iniquity is not done. There are other ways of robbing the Nicaraguans than through Presidential graft, and the American Government cannot afford to take a hand in a game played for the advantage of a few of its citizens in a foreign country. We are not apologizing for Zelaya; he is an intolerable anachronism; a monster, though parading in garments and etiquette borrowed from Paris: but it is not certain that his antagonists were altogether inspired by high moral purposes. Stability of government, however, is now assured, one way or the other, and the license of a dictatorial ruler will be restrained by assurances better guaranteed than those given in the Washington treaty for Central American arbitration and neutrality. Under such favoring conditions the mineral resources of Nicaragua will soon make of that country one of the great gold producers of the world.

The Prospectors' and Miners' Agency.

Pennsylvania is a great State. It is the home of the iron and steel industry. It has produced more coal and more coke than any other State in the Union. It has also produced a Quay and a wonderful State House, built for four million dollars "within the estimates," and furnished for more than three times that sum 'without estimates'. It is, finally, the home of the Prospectors' and Miners' Agency. Maybe you do not see the connection, but that is because you do not know the Prospectors' and Miners' Agency. This, according to its advertising matter, was organized in 1889, and since then has been engaged in manufacturing instruments "for tracing and locating treasures, mines, and minerals." The agency states that "we sell ten to every one of any other so-called instrument on the market." This is not altogether clear, but if it is to be interpreted that there are only one-tenth as many fools buying from others as from the Prospectors' and Miners' Agency, we sincerely hope it is so. Some way we are a bit chary of accepting some of the statements made by the agency. They are too good to be true. We have been accused of being too conservative, perhaps the reason for our doubts lies in this. We would like to believe—who wouldn't? There now is the wonderful "Goldometer—latest improved, patent applied for." It is clearly "a very convenient instrument for prospectors, miners, and treasure seekers," and is said to be "very powerful in locat-

ing the spot of underground treasures as its magnetic force always works perpendicular." Then there is the 'No. 2 Spanish needle'. Really a delightfully simple contrivance with separate points for iron, silver, and gold. You adjust the one you prefer and presto, there you are! Any one can find a mine! No, not quite any one, but, well, nearly everyone—nine out of ten, say. Owing to "lack of knowledge and magnetism" in the stray tenth man, the agency "cannot guarantee that each and every one will be equally successful." Of course not. We feel sure of that.

But listen to "what our customers say." P. M. M., for example, writes from Ramer, Alabama, under date of May 19, 1901, "I have discovered a silver mine on my plantation with this instrument, the miners and the minerolists value this mine at \$800,000." Now wouldn't that satisfy you? If not, how about this, from M. M. M., of Chapel, Mississippi, April 25, 1903, "I located the richest silver mine known—about 30 feet wide and about 40 miles long." No doubt about that certainly! Still we have not noticed that the silver output of either Alabama or Mississippi has increased since these discoveries. Perhaps this is magical silver and vanishes when brought to the surface. However, there is one statement made by the Prospectors' and Miners' Agency that we believe wholly and unreservedly: "We could continue to write testimonials like these until the number would run into thousands."

Possibly you are not interested in prospecting instruments. If not, how about a 'Treasure Ring'. What? Never heard of them? They are "commonly known as The Prospector's Ring or The Miner's Ring"—that fixes 'em for you surely. "'Tis said and claimed by many that this ring when worn while seeking for hidden treasures of any sort will aid them wonderfully in finding the exact spot quickly"—and only \$3, too! Not tempted even by this? You are a hard customer. We shall have to await the usual 'follow-up literature' before we know what to say to you. In the meantime we wonder how such literature gets through the mails.

The Cherry Coal Mine Disaster.

The mine fire at Cherry, Illinois, has proved one of the most serious of which there is record. The loss of nearly 300 men, with all that this means in the making of widows and orphans, is a disaster which from very magnitude has touched the hearts of all concerned in mining. Fortunately metal mines are not so prone either to explosions or fires as are collieries; nevertheless there are abundant lessons, applicable to other situations, to be drawn from the accident in Illinois. It is too soon, and we are too far from the scene, to attempt to fix the blame. That is the duty, under the law, of the State Inspectors; and those of Illinois are abundantly able to fulfil their duty in this, as in other directions. Lessons for the future may, however, be drawn, even if blame cannot yet be equitably portioned. The first and greatest lesson is the necessity for preparedness.

Accidents rarely, if ever, happen when and where they are anticipated, and the wise mine manager

must be eternally vigilant—always on the watch for the unexpected. Not only must he personally take this attitude but he must organize his corps of assistants so that each will know his place in case of fire, explosion, cave-in, or other accident. The value of this, and of frequent practise in anticipation of accidents, was splendidly shown in the case of the burning of the *St. Croix* which occurred almost contemporaneously with the Cherry accident. In the one case a steamer, out on the ocean, burned and sank. Ammonia fumes prevented a successful fight against the fire, but the disciplined officers and crew took the 300 inexperienced passengers to shore and safety without the loss of a life. Each man knew his place, discipline was perfect, and the disembarkation was carried on without a hitch. At Cherry the fire was underground; smoke and black-damp instead of ammonia interfered with fire-fighting. Discipline broke down and 300 men were lost. There seems to have been plenty of time, with right organization and generalship, to have got all the men out. Certainly it would have taken less time to have got the men out of the mine than the passengers off the *St. Croix*, and yet at the mine the lives were lost and on the steamer all were saved. However it may have seemed at the time, events prove that it was a mistake not to have called the men out of the mine at the first alarm of fire. It is better to lose a good many shifts than human lives.

In the second place, the mine organization should be like that of the army in providing a trained substitute for each man that falls. Apparently, at Cherry, when the bosses were fighting the fire on the second level, no one took their places as leaders elsewhere. The same lesson might have been learned at the Ziegler explosion a year earlier. There a number of the leaders being overcome while engaged in rescue work, none were available to take their place. Don't send all your officers on one charge! Keep a reserve, and have a flexible organization.

A third lesson to be learned is that of the value of discipline among the men themselves. The twenty-one that were rescued after a week's entombment came through alive because they submitted to be led. They obeyed orders. The men who died might, many of them at least, have been alive and well today had they not lost their heads and rushed into the most dangerous part of the mine. There is no question that discipline has been growing progressively weaker among the miners in Illinois, and probably elsewhere. This has been frequently charged to the influence of the labor unions. We are sorry to say that we believe there is substantial ground for this charge, but the fundamental trouble lies deeper. The breaking down of discipline through the union is only incidental to the fact that the coal mining industry in the Middle West has been run on so narrow a margin of profit that the operator has been in no position to stand for his rights. He has been obliged to keep going on almost any terms. The men, knowing this, and having in certain districts long arrears of petty injustices to pay off, have presumed on their position and made it difficult if not impossible to discharge a man as a means of

discipline. There can be little doubt that many of the lives lost will be found to have been sacrificed by someone's disobedience of orders. The engineer who refused to disobey orders and hoist the cage on which the rescue party burned to death, was right. More of that sort of spirit would in the end save lives.

Finally, it is interesting to observe that the judgment of the inspectors in ordering the shaft sealed was vindicated by the results. It was the only way, with the means at hand, to put out the fire, and no men could be rescued till the fire was conquered. The men who were saved adopted exactly the same tactics; they sealed themselves off from the fire and trusted to the air stored in the workings. Thus they gave the lie in the most direct fashion to the hysterical individuals who were shouting that the company was sacrificing the men to save the mine. It was the only way to save the men—but the men ought never to have been caught in such a trap.

The one cheerful feature of the whole situation is the intelligence and heroism displayed in the rescue work. The men who went down on the fatal last trip of the cage deserve the kindest thoughts of their fellow men, but these thoughts, too, should go out to those others who took equal risk and came out alive. To give the whole list would be impossible and with the data at hand the most deserving may well be omitted. We cannot forbear to mention Messrs. Tom Moses and James Taylor among the State Inspectors, R. Y. Williams and J. R. Webb, of the United States Geological Survey, Henry Smith and James Hand among the men. These, wearing the oxygen helmet, went down into the mine when conditions were wholly unknown and when, as was shown only too clearly at Cardiff in the same State, the greatest danger was to be anticipated. Their pioneer work, with doubtless that of others whose names have not come to us, made possible the re-opening of the shaft and the rescue of the men still living. Their work illustrates the usefulness of the helmets in advance work following an explosion. There should be a trained and equipped corps of men available in every mining camp, ready to respond to every call, like the old volunteer fire departments. These, and first aid corps such as have been organized in the anthracite districts, would do much to decrease the loss of life after an accident has occurred. To prevent accidents, which after all is the great desideratum, better organization, more study of the subject, and unceasing vigilance are needed. We recently had the pleasure of reviewing a little book by W. E. Garforth, who has done such excellent mine-rescue work in England, and were pleased to find that whereas the title was, 'Suggested Rules for Recovering Coal Mines After Explosions and Fires', a full third of the text was devoted to what to do before the accident occurs. That is the spirit in which work needs to be done, and as a valuable means of organizing and disseminating knowledge directed toward preventing mine accidents, we believe the present Technologic Branch of the United States Geological Survey should be expanded into a Bureau of Mines. The most expensive economy is that which seeks to economize knowledge.

TUNNEL DRIVING IN COLORADO.

Written for the MINING AND SCIENTIFIC PRESS
By H. FOSTER BAIN.

Colorado is becoming famous for its tunnels, a not unnatural result of its rough topography with high mountain ranges cut by deep canyons and gorges. Many of the railway lines pierce the mountains, and recently the longest tunnel in the United States, 30,-

experience has shown that long tunnels are too expensive to be undertaken for prospecting alone. Their utility lies in cheapening costs of production and rendering accessible orebodies already fairly assured.

The Newhouse tunnel, at Idaho Springs, and the Roosevelt, at Cripple Creek, are probably the most important among those now being driven in Colorado. The former was originally projected mainly as a transportation agency and only later came to

West End of Quartz Hill, Central City.

These mines are undercut at a depth of 1550 ft. by the Newhouse tunnel.

Russel Gulch, Gilpin County, Colorado.

The Old Town mine at the right is connected with the Newhouse tunnel by a 4000-ft. lateral.

582 ft. from portal to portal, has been completed near Montrose, Colorado, by the United States Reclamation Service. Of greater immediate interest to mining engineers are the long adits and cross-cuts found in nearly all the mining districts and which local custom designates as tunnels. The Revenue tunnel at Ouray, the Cowenhaven, at Aspen, and the Yak at Leadville, may be cited as types. Such tunnels are usually driven mainly to facilitate drainage of mines already well developed. To a subordinate degree they are expected to yield returns from cheaper transportation of ore, and to develop new ground. It is upon these claims that they must be justified since in Colorado, as elsewhere, repeated

take serious account of the possible revenue from drainage of wet mines. The Roosevelt tunnel, on the other hand, is primarily for drainage. It is to enable the orebodies to be followed downward another 740 ft. without the enormous expense of pumping. The Newhouse tunnel was begun in January, 1904, and has enjoyed but a halting rate of progress; periods of high-pressure work being followed by inactivity at the breast while negotiations were being conducted with some obdurate mine-owner. The Cripple Creek enterprise, on the other hand, has been driven forward almost steadily since its initiation. Apparently the two enterprises are to be completed at approximately the same date. The one will

give a new lease of life to Colorado's oldest gold camp, the other to its greatest.

At various periods since work on the Newhouse tunnel began, the methods of work have been changed either to reduce costs or to obtain greater speed in driving. Representative figures are available for work under three different systems. Details of the first were published in 1902.* For the two others they have been kindly supplied from the company books by George E. Collins, consulting engineer to the tunnel company. The Newhouse tunnel, formerly English owned, but now controlled by Boston stockholders, was designed to afford outlet to the mines of Gilpin county. These have attained a depth of approximately 2000 ft., measured on the vein, and show good ore at the bottom. The cost of pumping and hoisting, the lower grade of the ore, and the inadequate room and water for milling at Central City, all make such an outlet desirable. The portal of the tunnel is at Idaho Springs, in Clear Creek county, at an elevation of 7543 ft. and the tunnel is intended to run five miles slightly west of north. Something over four miles has now been driven and the breast is well under Nevadaville, in Gilpin county. Numerous veins have been cut and connection has been made with the surface through the Gem, Sun and Moon, Saratoga, and Old Town mines.

The rock in which the tunnel is driven is mainly granite-gneiss and mica-schist. Porphyry dikes occur and occasionally old conglomerates are found. In general the rock is exceedingly tough and gnarled, and the foliations dip away from the breast of the tunnel. The rock does not break beyond the bottom of the holes. The tunnel was begun by hand-labor, but power-drills were put in shortly after. At first these were used on one shift only, and a system was organized while Lafayette Hanchett was manager and S. A. Knowles foreman, which gave remarkable results. The drill crew worked only on day shift and remained on duty until the round was put in. The blasting was done by a second crew which also tore down the drills, laid pipe and track, and prepared the charges. A third crew followed and handled the broken rock, clearing up the breast and mounting the drills ready for the machine men. In order to make rapid progress by this method (and in fact excellent progress was made) it was necessary to drill and shoot long holes. Ten-foot holes were commonly drilled and 9 ft. at a round was broken steadily. This, of course, gave an immense amount of broken rock to handle, and made cleaning the breast slow work. It, however, took full advantage of the fact that much time is lost ordinarily in getting ready to drill and in tearing down after the round is in. In an eight-hour shift, as ordinarily organized, five hours or less are put in drilling. By the plan outlined full time was realized in the case of the most expensive men, the power plant had light duty except on one shift, and, since the blasting crew made all preparations before drilling was finished, there was ample opportunity for the smoke to clear without loss of time even of the cheaper men

working as shovelers. In order to hold the men to finish each round a particularly effective premium system of payment was devised whereby the men received increased wages in proportion to the work done at the same time that the cost to the company per foot fell. Without going into great detail it may be stated that by this method 2759½ ft. were driven in one year at a cost of \$28.80 per ft., and 2925 ft. another year at \$27.74. Of these sums the actual breaking costs, exclusive of permanent equipment, track, etc., were \$21.45 and \$19.68 respectively. The detailed cost per foot for a representative month may be quoted:

COST PER FOOT FOR MONTH ENDING AUGUST 31, 1909.

| | |
|--------------------------------------|--------|
| Labor: | |
| Drill crews and foremen..... | \$3.01 |
| Trammers, blasters, and drivers..... | 4.34 |
| Blacksmith shop | 1.03 |
| Engineers | 1.15 |
| Explosives | 4.55 |
| Oil and waste..... | 0.12 |
| Coal | 3.91 |
| Mules, feeding and shoeing..... | 0.32 |
| Drill repairs | 0.82 |
| Premiums | 1.87 |
| Tools | 0.33 |
| Timber | 0.16 |
| Track and material | 1.84 |
| Track—labor and repairs | 2.07 |
| Engineering and surveying | 0.22 |
| Salaries and office expenses | 1.97 |
| Legal expense | 0.07 |
| Insurance | 0.11 |
| Taxes | 0.12 |
| Minor items | 0.73 |

\$28.74

This work was done with Leyner drills, air at 160-lb. pressure. The holes were shot by battery, being loaded with 60% gelatine powder. The tunnel was double track and broken 12 by 12.

In 1902 the work was suspended and when again taken up a new plan was adopted. A contract was let to S. A. Knowles for breaking the rock, he furnishing labor and explosives. The cross-section was reduced to 9½ by 6 ft., except that provision was made for widening the tunnel at intervals to provide passing tracks. Under this contract between April 2 and December 31, 1906, 2128 ft. of advance was made including 360 ft. of double-track work. The minimum footage was 130 ft. in April, and the maximum 290 ft. in June. The average cost per foot is given below, the contractor being charged for air and transportation at the same rates as were other customers. As this afforded a small profit the actual expense was less than here given:

Cost per foot.

| | |
|--|---------|
| Contract price, including labor and ammunition.... | \$12.24 |
| Timbering and company labor..... | 0.15 |
| Power, compressed air, and ventilation..... | 2.41 |
| Blacksmith work | 1.72 |
| Drill repairs and steel..... | 1.38 |
| Other supplies furnished by the company..... | 1.09 |
| Transportation of rock and materials..... | 1.70 |
| Supervision and general expense..... | 0.92 |

\$21.61

In March, 1906, George E. Collins came to the company as consulting engineer and on the completion of the Knowles contract, took active charge as manager, a position he retained up to April 1909,

*H. F. Bain. 'Driving the Newhouse Tunnel', *The Engineering & Mining Journal*, April 19, 1902.

when R. B. Morton was made manager. In July, 1909, Mr. Morton resigned and the present organization, Mr. Collins, consulting engineer, R. C. Schirmer, assistant manager, Ralph Knowles, outside foreman, and Theo. Grasser, inside foreman, was effected.

The tunnel is now being driven with a 9½ by 5½ to 6-ft. cross-section, with wider cross-section to provide for passing tracks as needed, averaging about 200 ft. out of each 1000. The work is done on two shifts. The day shift includes a foreman, 2 drill-runners, 1 helper, 1 nipper, 4 shovelers, 1 trammer, 2 trackmen. The night shift is the same, except for the absence of foreman and trackmen. The shovelers go to work first and are expected to throw back enough rock so that the drill-men can put in a cross-bar over the top of the heap and go to work. The drill-men come to the portal at 6:30 a. m. They go in as far as the Saratoga station, where there is a dry-room, change clothes and then on to the face.

Newhouse Tunnel, Older Part.

They use two Leyner drills mounted on a cross-bar, and connect their air and water hose to a manifold on another bar across the face, about 8 ft. back, so as to keep the hose out of the way of the shovelers. Additional light bars are used to make a staging on which the drill-men stand and work. They drill about five hours actual time, putting in 20 to 22 holes involving 140 to 150 ft. of drilling, with air at 120 lb. pressure. The usual V-shaped centre cut is provided with holes looking down. In the meantime the shovelers work steadily, finally taking out the rock under the little platform on which the drillers work. The bar is then lowered and the bottom holes put in. The drills and steel are then loaded on a special car, pushed back out of the way, steel sheets laid, and the round blasted. Shooting usually comes about 3 p. m. In the bottom of each hole is put three sticks of blasting gelatine '100% powder'. This is followed by ordinary 40% dynamite, which is fired by cap and fuse, the cap being inserted in the dynamite

and the fuses cut so as to blast the cut first. The round broken varies from 4½ to 7 ft. The smoke is cleared by blower and high-pressure air from a 4-in. pipe. A mule is used in tramping back to the permanent track from which point an electric locomotive takes the cars in trains to the dump. Where the tunnel is to be broken wide for a passing track, one of the drills is turned to the side and puts in long holes looking away from the breast so as to slab off the side. The holes cost little extra and the additional width is gained cheaply. The method resembles in a way that used in railway work where a header is followed by bench drilling. The permanent track is laid close to the west wall, with 18-in. gauge, 35-lb. rails, and creosoted ties. To provide a water ditch the track is raised 12 to 18 inches and creosoted wooden blocks fitted in between the ties on the side next the ditch. By the new plan faster progress is made, and despite the greater distance from the portal, the cost per foot is less. The smaller cross-section allows only a single track, but this is ample for the traffic in this part of the tunnel.

Detailed distribution of costs for three months are given below:

| Items. | May. | June. | July. |
|---|---------|---------|---------|
| Labor | \$7.65 | \$5.59 | \$6.06 |
| Transportation | 1.42 | 1.34 | 1.34 |
| Power house — compressed | | | |
| air and blower | 2.15 | 1.79 | 1.86 |
| Blacksmithing | 2.35 | 1.18 | 1.22 |
| Explosives | 3.64 | 3.83 | 4.02 |
| Fuse and caps | 0.46 | 0.22 | 0.49 |
| Drill repairs | 1.24 | 1.02 | 0.93 |
| Use of machines and consumption of steel..... | 0.38 | 0.62 | 0.66 |
| Rail, ties, air for ventilation, pipes, broken wire.. | 1.59 | 1.58 | 1.66 |
| Sundries | 1.69 | 0.54 | 0.48 |
| Total | \$22.57 | \$17.71 | \$18.72 |

The footage and cost per foot for the early part of the present year are given below by the courtesy of Mr. Collins. In May the tunnel was being driven wide to provide for passing track. In June no permanent track was laid, and only the narrow cross-section maintained. In July there was 30 ft. of double track and some permanent track laying. In the same month three days were lost on account of the celebration of July 4.

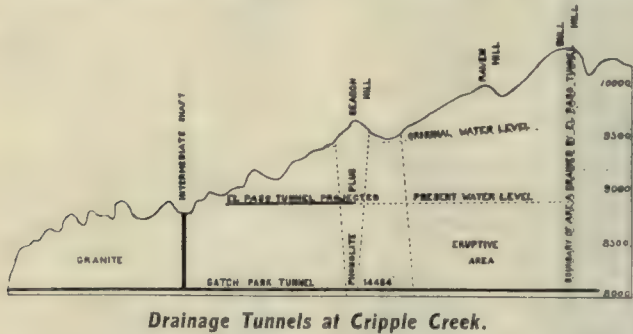

| | Distance. | Cost. |
|-----------|-----------|---------|
| January, | 291..... | \$22.66 |
| February, | 220..... | 20.41 |
| March, | 303..... | 17.48 |
| April, | 261..... | 22.87 |
| May, | 264..... | 22.57 |
| June, | 323..... | 17.71 |
| July, | 305..... | 18.72 |

As in the case of the previous figures the charges for power, transportation, and blacksmithing, are at the regular rates. The company now derives a substantial revenue from these charges, since there are a number of mines working through the tunnel. This includes the Gem, Saratoga, Old Town (connected with the tunnel by a 4000-ft. lateral), Sun and Moon, Druid (driving east through the Adduddel), Seaton Mountain, King Bee, Memphis and Idaho Springs, Gauntlet, and Adduddel. Veins be-

longing to a number of other companies have been cut, and arrangements for working them are being negotiated.

The Cripple Creek Drainage & Tunnel Co. was organized to drive a deep drainage tunnel to the heart of the productive district. For some time it had been apparent that the burden of pumping to reach lower horizons was bound to be a heavy one. The rocks which form the volcanic neck in which the veins of Cripple Creek occur, are so badly fissured and broken that the whole plug forms one vast sponge, and to work at any lower level, the ground-water throughout the area nearly three miles in diameter must be lowered. F. L. Ransome has figured that the discharge from one foot of subsidence in this district amounts to 35,000,000 gal. D. W. Brunton estimated that the various proposed tunnels would cost \$380,000 to \$570,000, or from \$628 to \$468 per vertical foot of depth drained, and would require 1.97 to 2.5 years to complete.

It was apparent that the task of providing drainage was peculiarly one for co-operative effort and accordingly after studies of the problem had been made by Seeley W. Mudd, D. W. Brunton, and others,

Drainage Tunnels at Cripple Creek.

it was determined to drive a deep-level tunnel. Stock in the tunnel project is held by the various mining companies somewhat in proportion to the supposed future distribution of benefits. In contrast with the stock in the Newhouse tunnel, it is not expected to pay dividends, and its purchase has been considered to be of the nature of an assessment. After 1400 ft. had been driven from the portal the further driving was contracted to A. E. Carlton at \$28 per ft., and since then nearly two miles of advance has been made. An intermediate shaft 650 ft. deep was sunk, it being opened September 15, 1908. For a time progress was made at three headings. In June, 1909, connection was made between the portal and the west drift from the shaft, since which time only one face has been available.

The cross-section of the tunnel-breast is 6 by 10 ft. A ditch 3 ft. deep is later excavated along one side, a single track being laid along the other. The pipe connecting with the blower is laid on top the ditch as are also the water and compressed air lines. The whole work is lighted by electricity. The rock through which the tunnel is cut is a blocky granite.

Work is organized in three shifts, each including drill-men, helpers, shovelers, and a driver. A mule is used for hauling the broken rock from the face to the shaft where it is hoisted in a self-dumping skip. Each crew includes 2 machine-runners, 2 helpers, 4 shovelers, and 1 machine-man working on the ditch. Leyner No. 7 drills are used, two in the breast and

one on a tripod at the ditch. The drill-men are paid \$4.50 per 8-hr. shift, and receive \$1 premium for each 5 ft. round broken with excess for more than 5 ft. The helpers get half as much premium as the machine-men. The holes are loaded with '100% powder' fired by means of one stick of Hercules powder primed with a 5X cap. The usual centre-cut system is used in breaking the ground. Since the work is done as a private contract, details of cost can not be published. Through the courtesy, however, of V. H. Mann, Mr. Carlton's assistant, I am permitted to give the following regarding the cost of supplies on the basis of an average for seven months:

| | Cost per foot. |
|--------------------------------|----------------|
| Powder | \$4.715 |
| Air-drills | 1.089 |
| Steel, shovels and picks | 1.505 |
| Candles | 0.178 |
| Oil and waste | 0.178 |
| Blacksmith supplies | 0.457 |

The rate of progress has been as follows:

| 1908. | Portal. | Shaft. |
|-------------------------|---------|-----------------|
| February 1 to April 1.. | 514 | ... |
| April | 262 | ... |
| May | 268 | ... |
| June | 187 | ... |
| July | 203 | ... |
| August | 303* | ... |
| September | 351 | ... |
| October | 287 | 49 1 heading. |
| November | 360 | 141 " |
| December | 334 | 177 " |
| 1909. | | |
| January | 435 | 261 " |
| February | 290 | 601 2 headings. |
| March | 340 | 639 " |
| April | 316 | 607 " |
| May | 402 | 552 " |
| June | 62 | 498 " |
| July | ... | 391 1 heading. |
| August | ... | 410 " |
| September | ... | 355 " |
| October | ... | 380 " |

*Began to use 100% powder.

Leyner drills were used at the portal from the first and at the shaft after January 15. The tunnel has now been driven 1140 ft., and has 3250 more to go. It is estimated that the breccia will be reached by September next, at which time the mines will begin to drain.

The Gunnison Reclamation tunnel, while not driven for mining purposes, was excavated by the same methods and is, therefore, to some extent comparable. It is 30,582 ft. long, and was begun in January, 1905, and finished July 6, 1909. A portion was driven by contract, but in the main, it was constructed by the engineers of the Reclamation Service.* It was cut through many different sorts of rock and methods were varied to meet the conditions. In the hard granite at the river portal, a heading 6 to 8 ft. high, and 12 wide, was carried with a 5 to 7 ft. bench. Sullivan 3-in. drills were used, four being mounted on two columns, each with a machine-man and helper. From 18 to 22 holes were necessary to a round. Three holes were used for the centre cut, 6 were 'relievers', 4 were side holes, 4 back holes, and

*For details, see I. W. McConnell, *Engineering Record*, August 28, 1909.

4 'lifters'. In addition 4 bench-holes looking down and away from the breast, were put in by an extra man with a tripod drill. At the breast each crew was expected to get in a round and clear the face in an 8-hr. shift. The bench was only broken on one shift. In other ground the organization was varied and Leyner drills were used. In the shale, Jeffrey coal augurs, air-driven, were employed and each crew got in two rounds of 12 holes per shift, there being two drills, with a runner and helper for each, on a shift. The rates of progress were extremely variable. In the shale, in 12 months ending July 1, 1906, 7500 ft. was driven with a three-shift organization. The best progress was 824 ft. For this ground 600 to 750 ft. per month was considered satisfactory. In the granite, in 1905, 384 ft. was undercut one month and in 1906, the full breast of the tunnel was advanced 392 ft. in one month. Later 449 ft. was made in one month. In general 300 ft. per month in the granite was regarded as good work. From the beginning to the end, the average progress was 566 ft. per month, or 255 ft. per 'gang-month'. The slowest progress was made in a belt of faulted ground where 50 ft. per month was considered very good. Many difficulties had to be overcome. In addition to heat and water, there were outflows of combustible gas and of carbon dioxide. An intermediate shaft was sunk to assist in the work and eventually a second had to be put down to secure adequate ventilation and temperatures low enough for good work.

The total cross-section inside the concrete lining, is 122 sq. ft. In driving this tunnel the methods were partly those of the mining engineer who drives either a full breast or a lower heading, and the railway engineer who drives an upper heading and carries a bench. In a general way the result seems to indicate that the choice of methods is properly determined by the area of the cross-section and in the case of the Reclamation tunnel, the area being between that of a railway and a mine tunnel, there was really small choice. The economy of driving by heading and bench where the cross-section will permit, is strikingly exemplified in one of the Wabash railway tunnels cited by H. P. Gillette,* where the costs per cubic yard were:

| | Heading. | Bench. |
|------------------|----------|--------|
| Drilling | \$0.48 | \$0.30 |
| Explosives | 0.30 | 0.20 |
| Mucking | 0.80 | 0.18 |
| Total | \$1.58 | \$0.68 |

It will be noted that while there is a slightly greater cost for drilling and shooting in the heading, due to the need of closer spacing of holes to break the same yardage, the big economy in bench-work comes from the cheaper handling of material, a direct result of the larger space. This reinforces the observation that greater speed in mine-tunnel driving is only to be obtained by better and speedier methods of handling the broken rock. Ground can now be drilled and broken faster than it can be cleared away. Gillette has suggested, arguing on the basis of experience in open-cut work, that in time mining

engineers may hope to decrease costs by working toward larger holes and heavier charges. If experience in mine-tunnel work is significant, there can be no question that at present the tendency is the other way. The remarkable improvement in drills has led to putting in smaller holes and more of them. The ground is thereby broken finer and the debris handled easier. So powerful and quick are the small drills now in use that the 2-shift and 3-shift systems are really economical and need no longer be defended on the basis of speed alone. In the cramped quarters of a mine-drift or cross-cut, short rounds and more of them are better. A satisfactory amount of drilling can be done even in the time left after 'mucking back'. A long drilling shift, such as was employed at the Newhouse in 1902, would result in more holes drilled than could be broken.

Chambering holes is also but little used underground and seems poorly adapted to small holes in hard, splintery ground, such as characterizes Western metal mines. The first explosion shatters the rock but packs it so tight in the hole that there is, with the means available, great loss of time in preparing a second shot. In some of the Lake Superior iron mines there is a tendency in the direction that Mr. Gillette indicates, as diamond-drills are used to put in long holes which are first 'sprung' and then shot with heavy charges. To most men with Western experience, however, the big stopes of the Lake Superior iron mines resemble out of doors more than a mine anyway, and until better means of handling material underground are perfected, it seems hardly likely that much effort will be expended in devising methods of shooting down larger blocks.

Standard hydrochloric acid solutions, according to Hulett and Bonner (*Jour. Am. Chem. Soc.* XXXI, p. 390), having a 'constant boiling' point is capable of use as a basis for volumetric work. Starting with an acid of almost any strength, and distilling, a point is soon reached where the degree of acidity in the retort and that condensed holds the same strength of acid. At 760 mm. pressure the density (at 25°C.) is 1.0962 and the strength 20.242% HCl, or 180.17 gm. of distillate will contain 36.47 gm. HCl. The boiling point is 108.54°C. The variations due to changes of barometric pressure likely to occur are not great. The table given is:

| Barometric pressure. | HCl, % | Gm. for 1 mol. HCl. |
|----------------------|--------|---------------------|
| 770 | 20.218 | 180.390 |
| 760 | 20.242 | 180.170 |
| 750 | 20.266 | 179.960 |
| 740 | 20.290 | 179.745 |
| 730 | 20.314 | 179.530 |

Starting with an acid of specific gravity 1.10 after distilling over three fourths, the succeeding distillate will not vary over 1 part in 1000 from the above figures.

A quick mode of decomposing minerals is to mix one part of the pulverized substance with one part of vaseline and 5 parts Na_2O_2 . Place the mass in a scorifier or on a thick iron plate and ignite with a match. On cooling, extract with water. The method is particularly suited for qualitative tests when in the field.

PUBLIC LANDS AND NEEDED LEGISLATION.

By RICHARD A. BALLINGER.

*The proper use and disposition of the public lands have raised questions involving no little legislative as well as administrative difficulty from the beginning of their history. The lands were, during the earliest administrations, treated as a national asset for the liquidation of the public debt and as a source of reward for our soldiers and sailors. Not until the discovery of gold on the Pacific slope did the policy change for one of exploitation, by which our citizens were encouraged to develop the mineral and agricultural resources of the public domain on condition of receiving limited areas at a nominal cost. To the same end, railway and wagon-road grants were liberally donated by Congress in order to add facilities for the opening up of these almost inaccessible regions.

The railway grants generally were limited to non-mineral lands, except such as contained coal and iron, which latter minerals were taken to be essential for railway construction and operation. New States were, when admitted, liberally endowed with public lands for school and other purposes; so that, out of a public domain in 1860 of 1,055,911,288 acres (Alaska then not belonging to the United States), we now have only about 731,354,081 acres, confined largely to the mountain ranges and the arid and semi-arid plains, except lands within some of the Indian reservations and the 368,035,975 acres of undisposed of land in Alaska. All of the principal land statutes were enacted over 25 years ago; the homestead act, the pre-emption, and the timber-culture act, the coal-land, and the mining acts for the aid of the industrious prospector, were among the earlier acts of this nature.

The liberal and rapid disposition of the public lands under these statutes, and the lax methods of administration which for a long time prevailed, naturally provoked the feeling that the public domain was legitimate spoil for the unscrupulous, and that it was no crime to violate or circumvent the land laws. It is to be regretted that the nation has been so tardy in realizing the importance of preventing our natural resources passing into the hands of land pirates and speculators, with no view to development looking to the national welfare. It may be safely said that millions of acres of timber and other lands have been unlawfully obtained, and it is also true that actions to recover such lands have in most instances long since been barred by the statute of limitations. The principal awakening to our wasteful course came under Mr. Roosevelt's administration. The bold and vigorous prosecutions of land frauds, through E. A. Hitchcock and J. R. Garfield, have restored a salutary respect for the law, and the public mind has rapidly grasped the importance of safeguarding the further disposition of the public lands in the interest of the public good as against private greed.

In this present policy of conserving the natural resources of the public domain, while development

is the keynote, the best thought of the day is not that development shall be by national agencies, but that wise utilization shall be secured through private enterprise under national supervision and control. Therefore, if material progress is to be made in securing the best use of our remaining public lands, Congress must be called upon to enact remedial legislation.

In order that intelligence shall be used in the disposition of the public lands, it is essential that they be classified according to their principal value or use. They have generally been classified in legislation as agricultural, mineral, desert, timber, and coal lands, and it is only in recent years that the Interior Department, through the Geological Survey, has undertaken to make this classification in the field in the aid of the administration of the statutes, and then only through the general authority given in the organization of this bureau. Specific legislative authority should be given the department to classify and segregate our public lands according to their greatest apparent use, with the continuing power of re-classification to meet changing conditions and the increased knowledge of their character which may necessitate the transfer of lands from time to time from the one class to the other. Full legal effect should be given such classification when made so as to prevent entries, under laws applicable to one class, of land belonging to another class, except after application for and a review of the classification; in other words, if lands are classified as coal lands, they should be enterable only as coal lands, and in case it be shown that they are improperly classified as coal lands and are, in fact, agricultural, they should then be enterable only as agricultural lands. This, to my mind, is the only way the Government can scientifically and effectively proceed to conserve the natural resources of the public domain. To leave to the self-interest of applicants the option to claim a particular tract of land as more valuable for mineral, agriculture, timber, phosphate, oil, or gas, or for power sites, is to invite confusion, fraud, and contention, and this has been the source of a major portion of the difficulties of the Interior Department in administering the public domain. It may seem at the outset that this would be a radical departure, to the extent of suspending the disposition of public lands pending their classification, but, as a matter of fact, a large portion of the unsold public land has already been classified by the department, but such classification has not the authoritative basis or effect to accomplish the result above outlined.

As to minerals, other than those hereinafter specified, because of the manner of their occurrence, doubtless no effective classification can be made in advance of discovery, and they should for that reason be treated as an exception in classification and dealt with accordingly.

The present coal-land laws respecting the States and Territories, as well as Alaska, should be supplanted by an act fully meeting existing as well as future conditions. The inducements for much of the crime and fraud, both constructive and actual, committed under the present system can be pre-

*Abstract from Annual Report as Secretary of the Interior, for the year 1909.

vented by separating the right to mine from the title to the soil. The surface would thereby be open to entry under other laws according to its character and subject to the right to extract the coal. The object to be attained in any such legislation is to conserve the coal deposits as a public utility and to prevent monopoly or extortion in their disposition. This may be accomplished either through a leasing system, by which the title would remain in the Government, under proper regulation and supervision by the Secretary of the Interior, or through the sale of the deposits, and in either case with restrictions on their mining and use which would control the minimum output and conserve the deposits as a public utility. I believe the most advantageous method will be found in a measure authorizing the lease or sale of the coal deposits in the lands, subject to forfeiture if the rights granted be not exercised under any reasonable regulations imposed. An exploration period of at least one year upon a permit basis, at a nominal charge, would insure to the applicant the necessary preliminary knowledge upon which to make the lease or purchase of the coal deposits and venture the necessary investment for operation. The maximum unit authorized for this use could safely be made from three to five sections, provided no greater surface rights be granted than will give proper facilities to reach and extract the coal deposits. In case of failure of the lessees or grantees to open and operate the coal deposits under reasonable limitations and to maintain an output reasonably suited to the deposits, and in case of combinations as to price or limitation of output, title should be forfeited by proceedings in court for that purpose. Government mine supervision would doubtless be necessary to enforce the conditions and limitations under the grant.

The above suggestions with reference to the disposition of coal deposits are equally applicable to the oil and gas fields in the public domain, and similar legislation as to lands containing the same is hereby recommended. Indeed, the very nature of these two important mineral resources requires that their disposition be in terms of quantity of the product extracted rather than of acreage.

Pending the enactment of new legislation as affecting coal lands, all known coal areas were withdrawn from entry for classification and appraisalment through the Geological Survey. April 10, 1909, I changed to a practical and scientific basis the system of classification and valuation for disposition of coal lands under existing laws. For the purposes of classification and valuation, the coal deposits are divided into four classes in accordance with their fuel value and the thickness and depth of the coal beds. The prices of the lands are determined on the basis of an estimated tonnage and range from $\frac{1}{2}$ to 3c. per estimated ton, in accordance with the quality, thickness, and situation of the coal. Provision is also made for taking into consideration in making the valuation any special conditions enhancing the value of the land for coal mining purposes; also, for a review of the classification or valuation upon proper application and showing to the department.

The classification and appraisalment of the coal lands in the States and Territories other than Alaska proceed upon the authority of the act of March 2, 1873, which fixes the minimum price only for lands and leaves to the Secretary of the Interior their appraisalment and the determination of their maximum value. In view of the fact that the law of Alaska directs the disposition of the coal lands in that Territory at the flat rate of \$10 per acre, no such classification or appraisalment is warranted by existing law.

I have recently withdrawn temporarily, for the purpose of submitting the subject to Congress for new legislation, large areas of oil lands in Wyoming, California, Utah, and Oregon. I desire to call attention to the importance of asking Congress to authorize the Executive to reserve certain areas of these lands for the purpose of affording a supply of fuel oil for the future use of the navy, and to make such regulations as may be necessary for the preservation and extraction of such deposits. No legislation exists for the entry of oil and gas lands other than the general mining laws of the United States, which are not adaptable to the disposition of lands containing mineral oils and gas.

Under the previous administration there were temporarily withdrawn, pending action by Congress, 4,702,520 acres of land in the States of Wyoming, Idaho, and Utah, as containing phosphate deposits. These lands are being re-examined by the Geological Survey at my direction with a view to eliminating all tracts not containing such deposits. The area of the original withdrawals has now been reduced to 4,471,480 acres by the elimination of non-phosphate lands, and I am advised by the classifying officers that additional areas will be eliminated as a result of their examination. The lands containing phosphate are not adaptable to disposition, and should not be allowed to be disposed of as either placer or lode mineral claims, but the deposits should be leased or sold in limited areas and on conditions preventing monopoly and insuring domestic use.

In anticipation of new legislation by Congress to prevent the acquisition of power sites on the public domain by private persons or corporations with the view of monopolizing or adversely controlling them against the public interest, there have been temporarily withdrawn from all forms of entry approximately 603,355 acres, covering all locations known to possess power possibilities on unappropriated lands outside of national forests. Without such withdrawals these sites would be enterable under existing laws, and their patenting would leave the General Government powerless to impose any limitations as to their use. If the Federal Government desires to exercise control or supervision over water-power development on the public domain, it can only do so by limitations imposed upon the disposal of power and reservoir sites upon the public lands, the waters of the streams being subject to State jurisdiction in their appropriation and beneficial use. I would, therefore, advise that the Congress be asked to enact a measure that will authorize the classification of all lands capable of being used for water-power development, and to direct their dis-

posals, through this department, under substantially the following conditions: (1) That the title to such lands be reserved in the Federal Government, and only an easement granted for the purpose of developing and transmitting electrical power for private and public use, and for the storage of waters for power, irrigation, and other uses. (2) That such easement be granted for a limited period, with a maximum of at least 30 years, and the option of renewal for stated periods upon agreed terms. (3) That entry shall be accompanied by plans and specifications covering the works sought to be installed, and covering the maximum horse-power capable of development at such site; also, that a substantial entry fee be paid to show good faith, and that a transfer to the United States of the necessary water rights to permit of the estimated power development be made. (4) That the construction period allowed entrymen for the development of at least 25% of such power shall not extend beyond four years, or such further time as may be granted by the Secretary of the Interior upon a proper showing. (5) That a moderate charge shall be made on the capital invested, or upon the gross earnings of the project for the first ten years of operation, adjusted at each subsequent ten-year period, and equitably determined by appraisalment. (6) That all rights and easements shall be forfeitable for failure to make development within the limitations imposed or upon entry into any contract or combination to charge or fix rates beyond a reasonable profit on the investment and cost of operation, or entry into any agreement or combination to limit the supply of electrical current, or failure to operate the plant. (7) That all books and accounts shall always be subject to the inspection of the department.

Unreasonable or narrow restrictions beyond the necessity of public protection against monopoly, or extortion in charges, will, of course, defeat development and serve no useful purpose. The statute should, therefore, while giving full public protection against the abuses of the privileges extended, so far as consistent, encourage investment in these projects; and it must always be borne in mind that excessive charges for the franchise will fall upon the consumer. Legislation of this character proceeds upon the theory that Congress can impose such contractual terms and conditions as it sees fit in the sale or use permitted of Government lands so long as such limitations do not conflict with the powers properly exercised by the State wherein they may be situated.

Alaska has now a permanent white population estimated at 33,000. There are in addition 7000 employed in the mines, canneries, and in railroad construction who are transients, and about 35,000 natives. Coal is widely distributed throughout the district, but up to the present time practically no production has occurred and no patents for coal lands have been issued. One hundred and sixty-five miles of wagon roads, 383 miles of sled roads, and 241 miles of trail have been constructed, at an approximate cost of \$690,000.

The rapid development of the mineral wealth of Alaska and the establishment of transportation fa-

cilities is attracting and will continue to attract a constantly increasing permanent population to the district. This creates an increased demand for agricultural products, which can be met in part by local production provided proper encouragement is given to the settler to enter, improve, and develop lands suitable for agriculture and grazing. The approximate area of agricultural and grazing lands ranges from 16,700 to 28,000 sq. mi., and the known coal fields embrace about 12,000 sq. mi., of which about 7000 could be covered by a system of surveys planned to include the agricultural and grazing lands mentioned. It is very important, in the interest of agricultural development, that the system of public-land surveys be extended over lands of this character, as, in the absence of such surveys, the present cost of acquiring title under the homestead laws is prohibitive except in the most favored localities.

The lands described are widely distributed over a region containing some 200,000 square miles; the cost of surveys in this field will be large because of the high cost of transportation and the shortness of the open season, and to promote the development and encourage the settlers it is important that results should be obtained at the earliest possible date. Many of the difficulties which would attend the making of surveys in the manner now in vogue in the United States proper can be avoided by providing for a geodetic control of surveys through triangulation. This will enable the taking up of sub-divisional work in the most important areas first, and yet the entire area can be included in one system of surveys. With a slight additional cost the triangulation can be extended into the important mining districts and monuments established to which all private surveys for land may be connected, thus avoiding litigation and confusion in the future on questions relating to boundaries. The geodetic methods of survey have been applied in the sub-divisional survey work of various Indian land surveys during the past 20 years and have worked expeditiously and successfully. I, therefore, respectfully recommend that the necessary appropriations be made for the initiation of this most important work, and that the Secretary of the Interior be authorized to carry on these surveys by engineers in his department.

WORLD'S PETROLEUM PRODUCTION.

The following table shows the world's production of crude petroleum in 1904 and 1908 and the share of the United States and other countries, according to figures compiled by the United States Geological Survey:

| Countries. | 1904. | | 1908. | |
|-----------------------------|--------------|-----------|--------------|-----------|
| | Million bbl. | Per cent. | Million bbl. | Per cent. |
| United States | 117.1 | 53.4 | 179.6 | 63.1 |
| Russia | 78.5 | 35.8 | 62.2 | 21.9 |
| Sumatra, Java, and Borneo.. | 7.7 | 3.5 | 8.8 | 3.1 |
| Galicia | 5.9 | 2.7 | 12.6 | 4.4 |
| Rumania | 3.6 | 1.6 | 8.3 | 2.9 |
| India | 3.4 | 1.5 | 5.0 | 1.8 |
| Japan | 1.4 | 0.7 | 2.1 | 0.7 |
| Mexico | ... | ... | 3.5 | 1.2 |
| All other | 1.7 | 0.8 | 2.5 | 0.9 |
| Total | 219.3 | 100.0 | 284.6 | 100.0 |

OUTCROP OF OREBODIES.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. EMMONS.*

The outcrops of orebodies are of special interest since it is through them that most deposits are discovered. Now and then a 'blind lode' is uncovered by a chance excavation, or through some fortuitous circumstance the true character of an outcrop may be recognized. Such was the case at Cobalt, where the first discoveries were made while grading for a railroad, but chance discoveries are rare indeed, compared with those which are made by prospectors with whom exploration is a business. The discovery of the outcrop of the ore, and the first recognition of its meaning, are events of prime importance in connection with the economic history of a mining district, and as a rule one may learn a good deal about the outcrop of the ore first discovered by referring to a reliable history of the district. Although there are orebodies which do not outcrop, most of these are discovered after the value of outcropping deposits has been proved in the same district. It is not considered good practice to attempt deep exploration unless there are exposures in the district at the surface or in the shallow workings which promise reward for deeper and more expensive prospecting.

Outcrops are interesting also because these portions of the deposits have had, as a rule, a more eventful geological history than any other part, and they are situated at the surface of the earth where changes are most rapid. An outcrop may represent a portion of the deposit which has once been primary ore and which later has become the zone of sulphide enrichment; at a still later date, the zone of oxidized sulphides; and later still the zone of leached oxides. Last of all, as the surface is worn away, the deposit also is denuded. The component materials are broken up and carried away, either in solution or mechanically. If in solution, they may enrich the deposit lower down, or they may join the general surface circulation and be scattered. If they are removed mechanically the heavier portions may accumulate as placers, or if the conditions for this are unfavorable they may be lost. Thus the cycle is completed. The study of outcrops is a study of the effects of weathering and erosion of ore deposits. The effects of weathering are shown in the topographic expression of the outcrop, and in the composition of the oxidized zone, in general, and with respect to value.

The topographic expression of lode-deposits depends upon the difference in the rates at which the deposit and the country rock are eroded. If the deposit is more resistant to erosion than the country rock, the latter will be removed more rapidly and the lode may outcrop as a ridge or knob. If the country rock is more resistant than the orebody, then the deposit may occur at the bottom of a slight depression where blocks of hard vein-quartz are mingled with the rock débris. If there is no marked difference between the rate of weathering of the deposit and the rate of weathering of the country rock, the deposits may be found in any topographic position, and for the

lode-deposits of the western part of the United States, this is most common. There seldom is here a conspicuous relationship between the outcrop of the deposits and the large features of the topography, although in many California camps, and in some of the Nevada camps, as at Goldfield and at Mineral Hill, some of the minor features of the relief may be controlled by the lodes.

It is not unusual to find differences in the character of topographic expression of the deposits of a single district, or even in a single lode. At one place it may outcrop as a ridge, in another along a ravine. The difference must be great before considerable permanent relief is established, for the rock of a ridge is in an exposed position, and is, therefore, the more readily attacked by agents of weathering. The great majority of the orebodies are lode-deposits. They are for the most part rudely tabular, and there is accordingly a tendency for their intersection with the surface to be expressed as a line usually curved,

Fig. 1. Outcrop of a Lode in Steins Pass District, New Mexico.

(Photo., Graton, U. S. G. S.)

the curvature depending upon the topography and the dip of the lode, or upon an actual bend of the lode along the strike. The relief is variable, and is an expression of the relative rate of erosion of the lode and country rock. Fig. 1 shows a conspicuously outcropping lode.

With respect to the ratio of the rates of erosion of the lode-deposits and the country rock, it is unsafe to make too sweeping generalizations, for the rate of erosion of each depends upon many variables aside from composition; but there are some more or less constant features which should be recognized. For the sake of comparison the deposits may be loosely grouped as follows:

- (1.) Silicious lodes in limestone or other soluble or easily eroded rocks.
- (2.) Pyrite-rich lodes in limestone or other soluble rocks.
- (3.) Silicious deposits in igneous rocks (granites, porphyries, etc.).
- (4.) Quartz-pyrite lodes in granites or in porphyries.
- (5.) Silicious deposits in quartzites.

*Published by permission of the Director of the United States Geological Survey.

(6.) Pyrite-rich deposits in quartzites.

(1.) As a rule the highly silicious ores in limestone and other soluble rocks outcrop conspicuously above the surrounding country. The difference in the rate of erosion of the ore and country rock is probably a maximum for such deposits, consequently these deposits are often the first to be recognized, and many camps in the western part of the United States owe their discovery to them. The Hope mine, at Philipsburg, Montana; the Mineral Hill mine, in Eureka county, Nevada; the original Bullfrog mine at Bullfrog, Nevada; (Fig. 2), the quartz outcrops in serpentine along the Mother Lode of California; some of the lodes of the San Juan in Colorado, and many other deposits, may be cited as examples of boldly outcropping quartz bodies which are bounded on one or both sides by limestone or by other rocks which are eroded at a relatively rapid rate. Most of these deposits contain a high percentage of quartz, and the ore commonly contains more than 90% silica. If the calcareous wall-rock has undergone much metamorphism it is more resistant to erosion than before, and the outcrops are usually less conspicuous.

(2.) As pyrite increases in such deposits the outcrop is likely to be less conspicuous. The pyrite alters to the hydrous iron oxide, limonite. This alteration is attended by a loss of sulphur and some iron, which substances are removed as iron sulphate; there is also an addition of oxygen and water. As a result there is a loss of volume, as is shown by pseudomorphs of limonite after pyrite, which when broken open are usually found to be cellular. Although limonite is relatively insoluble in the common underground waters—perhaps even less soluble than silica, the oxidation may leave a powdery mass which is easily washed away, and as a result the pyritic cropping is nearly always less resistant than the limestone wall-rock. Accordingly the highly pyritic deposits will outcrop in slight depressions or on hillsides. Lodes of highly pyritic gold ore and pyritic copper seldom stand up conspicuously above the surface of limestone, but are recognized from the color of the surface rather than its relief.

(3.) Silicious deposits in igneous rocks are eroded by earth-waters at a rate which on the whole is little less rapid than the erosion of the country rock. As a result such deposits are likely to outcrop above the general surface, but the outcrops are not so conspicuous as those of the silicious deposits in limestone. The difference is not so great as the difference between the erosion of silicious ores in limestone, nor is it so nearly uniform. It depends in a larger measure upon the extent to which the silicious lode has been fractured since it was deposited, and if fracturing has been extensive, such a deposit may be eroded at a more rapid rate than the igneous rock; indeed, a part of such a deposit may form a conspicuous depression, especially where the lode crosses a ridge, although other portions in which the ore is less fractured may outcrop a little above the surface. On the other hand, certain kinds of hydrothermal metamorphism of the igneous rock, and structural features such as jointing, sheeting, and vesicularity, may make it more easily eroded and then the deposit may outcrop as a ridge. An outcrop

of a silicious orebody in eruptive rocks is illustrated in Fig. 3.

(4.) Pyritic lodes in igneous rocks are usually eroded more rapidly than the rock. As pyrite increases in the lodes which cut the porphyries and other igneous rocks, their outcrop becomes less conspicuous, and if much pyrite is present these deposits are likely to lie a few feet below the level of the country. Between the silicious and pyritic lodes is a great class of deposits which carry considerable quartz and also a notable amount of pyrite, and such deposits are likely to be eroded at about the same rate as the country. Outcrops of this character are numerous, and perhaps they exceed all others. The presence of the lode is not indicated by any constant topographic feature. At most places there is not the slightest ridge or the faintest depression, but here and there, perhaps, or at only one place along the lode, the adjacent country rock may have been ground up by movement, which nearly everywhere follows the walls of the veins more or less closely. If the post-mineral fissuring has left the vein for the country rock in only one favorable place, that circumstance may be responsible for a little more rapid erosion at that place, making an exposure of the lode. Many of these lodes are found where they are crossed by small canyons or in cliff exposures due to other causes, or by following float up the hillside and trenching here and there for the lode, or again by investigating small depressions or other areas in which the loose soil and rock are stained by limonite. Butte and Granite, in Montana, afford good examples of lodes in igneous rocks which may at one place outcrop just a trifle above the general surface, but which at other places on the same lode may be found below a slight depression. In both these districts there has been considerable post-mineral fissuring which in the main follows the lodes. With a few exceptions there are no long continuous outcrops of lodes in either of these camps. Here and there a slight depression may mark the apex of the lode, but at most places there is not enough difference between the rate of erosion of the ore and country rock to find expression in the topography.

(5.) Silicious deposits in quartzite weather at about the same rate as the quartzite, and the problem of their discovery is similar to that of the lodes just considered.

(6.) If, however, there is a notable amount of pyrite in the ore it weathers more rapidly than the quartzite, and as a result the apex of the deposit is obscured. Quartzite, on account of its erosion-resisting qualities, is an unfavorable rock for ore outcrops, and this fact, together with its comparative insolubility in most replacing solutions, probably justifies the prejudice against it which exists in the mind of the prospector. While a few important deposits have been found in quartzite, their number is small, indeed, compared to the deposits which have been discovered in limestone and in igneous rocks. Perhaps this difference is emphasized in no small degree by the unfavorable conditions controlling outcrops.

Orebody which are less resistant to weathering

processes than the country rock are, as already stated, difficult to find. A long depression in such a position that it does not seem to be a natural drainage-channel may cover such a deposit and should be trenched for investigation. When deposits of this nature have been found and followed a short distance underground it is good practice to outline with pegs the trace or apex of the orebody on the surface, and to peg out in both directions the position which the orebody would take if its dip and strike remain unchanged. In this way it may be followed through outcrops of country rock and over grassy unexposed portions of the surface, and by trenching it may be found. In a hilly country with veins which are not vertical, it is convenient to use a plane-table and a flat board for sighting. The table is placed on the apex of the lode and leveled. A thin board is trimmed to an angle corresponding to the dip of the vein and a second rectangular board is placed against this on the plane-table so that its upper edge points in the direction of the strike of the lode. It is then oriented exactly with the lode, and by sighting along it pegs may be driven anywhere on the hillside, and should be exactly on the apex of the extension of the lode providing its attitude remains unchanged. If its attitude does change, the change is often shown by outcrops of country rock in the strike of the extension shown by sighting along the board.

Changes in depth as indicated by outcrops. To some extent the difference in the rate of erosion of the ore and country rock may give a hint as to the relative size of the lode in depth. If the deposit varies greatly in width down the dip and if it is eroded much less rapidly than the country rock, then in a majority of cases its width will decrease in depth. If, on the other hand, the country rock is eroded less rapidly than the deposit and the lode varies in width down the dip, its width will increase in a majority of cases. If the lode is very resistant and the country rock easily eroded, then the lode

rock and outcrops as a ridge. The solid line, which is an erosion-surface showing a maximum amount of the hard rock, may be called a permanent surface, while the dotted line, showing a maximum amount of the soft rock, may be called a temporary surface.

Fig. 3. Surface Workings of the Anaconda Vein, Cripple Creek, Colorado.

The lode is a sheeted zone of silicious tellurium ore and the country rock is volcanic breccia.

(U. S. G. S. After Lindgren and Ransome.)

If, on the other hand, the deposit be less resistant than the country rock, and if it vary in width down the dip, the narrow portion is likely to remain at the surface longer, as shown by Fig. 7, where the

solid line represents the 'permanent' outcrop, and the dotted line the 'temporary' outcrop. Such a deposit is likely to increase in size as it is followed downward. In other words, the erosion is such that a maximum amount of the most resistant material, be it ore or country rock, tends to remain longest at the surface, and as far as possible to monopolize the outcrop. Not all, but the majority of such deposits will increase in size with depth. Examples where large masses of quartz outcropping in limestone are underlaid by relatively small bodies of quartz in limestone are common. Among such deposits are the lodes of Mineral Hill, Nevada, the Cadgie Taylor mine, Montana, and many other deposits of silicious ore in soluble rocks.

On the other hand, some of the soft lodes of fissured decomposed quartz and clay which outcrop at Bullfrog, Nevada, in relatively resistant rhyolite, have shown a fairly consistent tendency to increase in width down the dip of the deposit from the apex to near the bottom of the oxidized zone.

Composition of outcrops and leached zones. Since

Fig. 2. Outcrop of Original Bullfrog Lode.

The small hill in the foreground is composed in part of solid quartz which dips at an angle. The country rock is rhyolite and limestone.

(U. S. G. S. After Ransome, Emmons, and Garrey.)

outcrops above the surface, and the wider part of the lode will outcrop for a longer period of time than the narrower part, hence, if there be several deposits of this character, most of them will be found at a time when a maximum amount of the hard rock is exposed to erosion. Fig. 6 illustrates this case. The lode is more resistant to erosion than the country

pyrite is an important constituent in nearly all primary gold, silver, and copper ores, the color of the oxidized outcrop is red or brownish yellow, depending upon the amount of limonite present. Brown shades may be shown locally, due to manganese stains, as at Bullfrog and Manhattan, Nevada; or if this oxide is in great quantity the color may be black, as at the outcrops of some deposits at Philipsburg, Montana. The composition of the oxidized zones is discussed authoritatively by R. A. F. Penrose, Jr., in his paper on the 'Surface Alterations of Ore Deposits'.¹ The minerals of the outcrops and oxidized zones are the residual primary minerals which remain behind owing to their relative insolubility and to the secondary minerals formed by oxidation and kindred processes. The residual minerals are essentially those which commonly occur in placers, and include gold, platinum, cassiterite, rutile, zircon, and some gems. In addition to these minerals galena and quartz are often found. These substances are much less soluble than pyrite, zinc blende, and antimony sulphide, and so may be found as small remnants at or near the surface, mingled with the minerals of the oxide-zone, and at some places they may be found in placers.

Magnetite and specularite resist the agents of

Fig. 6.

weathering longer than pyrite, and in deposits where the three occur together the magnetite and pyrite may appear at the outcrop, together with a considerable quantity of limonite, which is an alteration product from pyrite. The pseudomorphs of limonite after pyrite may be intergrown with the residual magnetite. Galena is dissolved slowly and is often found in an unaltered condition. Enargite seems to be one of the most insoluble minerals and so in the few deposits where it is a primary mineral it may appear in or just below the outcrop. At places in Tintic, Utah, according to L. C. Graton, pyrite, chalcocopyrite, and other sulphides have been dissolved out of the higher zones, and galena and enargite only remain. At other places enargite remains and galena has been dissolved.

Secondary minerals formed in the oxidized zone by oxidation and kindred processes are given below. The amounts of these minerals vary greatly, depend-

ing upon the composition of the ore before oxidation, upon the relative solubility of the minerals, and upon the earth-waters causing weathering, the nature of the country rock, and upon other conditions and processes.

Native elements: Amalgam, antimony, arsenic, bismuth, copper, gold, lead, mercury, silver, sulphur, tin.

Oxides: Bauxite, cuprite, hematite, kaolin, limonite, magnetite, melaconite, molybdate, psilomelane, pyrolusite, turgite.

Sulphates: Alum, alunite, caledonite, celestite, chalcantite, goslarite, leadhillite, gypsum (barite and strontianite in part).

Carbonates: (Ankerite), aragonite, aurichalcite, azurite, calcite, cerussite, dolomite, hydrozincite, leadhillite, siderite, smithsonite, witherite, magnesite.

Silicates: Calamine, chalcedony, chrysocolla, chert, opal.

Phosphates: Pyromorphite, pseudomalachite.

Chlorides: Cerargyrite, pyromorphite, alacamite, bromyrite, calomel.

Many of these minerals are the result of the oxidation of the primary sulphide ore, but some result from oxidation, reduction, or chloridation of the secondary sulphides. This is true in a large measure of the rich copper and silver minerals.

Extent of the oxidized zone. In countries which have been glaciated in the last glacial period the sulphide ores often outcrop at the surface. In Alaska and in New England, where the ice erosion was vigorous, such outcrops are most common. If any extensive oxidation took place below the ice the oxidized ore was removed by ice-erosion.

For countries which have not been recently glaciated the vertical extent of the oxidized zone depends, in a broad way, upon the depth of the water-table below the surface. Oxidation may take place below the water-table, but this is not often pronounced, and may be regarded as an interesting feature rather than as an economically important one. Often, the bottom of the oxidized zone is above the water-table. This is particularly the case where the lode is little fractured. It is likewise true where the water-table has lately been depressed through change of climate to aridity, as in the Great Basin of the United States, or where stream beds through which the lodes are drained are being rapidly lowered by erosion, as is often the case in mountainous regions. Indeed it is common to find the sulphide ores marooned high above the water-table, and these may oxidize in place to rich silver and copper minerals. S. F. Emmons² has divided the oxidized zone into two sub-zones, the lower zone of rich oxidized ore, and the upper zone of leached oxides. The depth of the latter is controlled to some extent by the position of the water-table, but depends mainly upon processes of leaching which are discussed below. The presence of this zone is quite generally recognized, but data relating to its depth are obviously of considerable importance, especially to the prospector or to the miner who is engaged in opening a property.

WHITE RIVER COPPER PROPERTIES.

Written for the MINING AND SCIENTIFIC PRESS
By GUY A. R. LEWINGTON.

Convincing indications of an era of development are now shown on the upper White river properties, where primary native copper occurs in the amygdulose of zeolitic amygdaloids, traceable along the north-east side of the Wrangell mountains for more than five miles. The principal locations at present are the Jack Dalton, the Bob Wiley, and the Boorman group. The last is represented on the ground by two men, Sinclair and Hutchings, who were the first to

cuprite, and traces of gold and silver have been found at this point. From surface indications there appears to be a zone of copper minerals of considerable magnitude in this particular region. Near the International boundary line, and on the Canadian side, is what is known as Discovery claim. Henry Bratnober has visited it several times. A good showing is to be seen here. Many claims have been located around Discovery, but little development has been done to date. On Rabbit creek, at a point near the Boundary line, and about five miles north of White river, is a prominent outcrop about 40 ft. wide, iron-stained, with blue and green carbonates of cop-

Map Showing White River District, Alaska.

(After U. S. G. S.)

leave Dawson last spring for the purpose of doing development work. They left on March 10 and took with them 6000 lb. of supplies, and they will continue development through the coming winter. The Boorman group is represented by 19 locations. The croppings on all of these properties occur at an elevation of about 5000 ft., or 1500 ft. above the creek level, and are situated some 40 miles east of the famous Bonanza group on the Nizina, a tributary of the Copper river. The latter property is controlled by the Guggenheims and J. P. Morgan, and they are spending \$20,000,000 in development, including the railroad up the Copper river.

Most of the development work is being done on the line of the Washington and Red Fox claims on Moraine creek by Sinclair and Hutchings, who are driving an adit to tap the outcrop some 50 ft. in depth. High-grade ore with native copper and

per and chalcopyrite. Some 30 ft. of tunnel has been run.

At Benson, on Beaver creek, a tributary of Snag, about 35 miles north of White river, a number of strong veins of free-milling gold ore are situated and some development has been done. These camps are awaiting the construction of the Copper River & North Western railroad over Seoli pass, which will enable supplies to be delivered. There is another favorable route for a railroad from the coast, with a deep-water harbor at Haines mission on Lynn Canal, the highest divide being approximately 3250 ft. above sea-level, with comparatively easy grades and plenty of timber. This route is worthy of consideration in the development of this part of Alaska and of the Yukon Territory, it would open much valuable country that cannot well be reached by any railroad now building, or, so far as I know, contemplated.

This region offers a promising tonnage for more than one road, as there is an immense stretch of country that is undoubtedly rich in minerals.

The White river, which empties into the Yukon some 90 miles above Dawson, has proved navigable for small steamers for a distance of 150 miles, the steamer *La France* (one of the smallest Yukon river boats) having made a trip this summer of 100 miles up-stream, and later the *Pauline*, a somewhat smaller boat, managed to get up 150 miles. A light-draft steamer, drawing about 15 in., with good power and a capacity of 20 tons, can, it is now felt, reach the copper mines on the White river, and possibly Kluane lake, where good placer diggings exist. Freight rates are now 20c. to Kluane, and 50c. per pound to the head of White river.

All the properties at the head of the White river are distant from White Horse about 300 miles; from Coffee creek on the Yukon river it is about 150 miles; and from Dawson to the head of navigation by steamer on the White leaves only a distance of 50 miles of trail. This last would seem to be the best way to get in during the summer season, but so far there is no boat on this run, and it cannot be depended on. The Coffee creek trail has not been much traveled, so that any one contemplating a summer trip to this district should go in from White Horse, as there is a good wagon-road more than half the way, and a well traveled trail the remainder. In all cases a stranger should have a guide. There is scarcely any doubt that this part of the Yukon Territory and Alaska has a great future.

RELATIVE MERITS OF ACID AND BASIC PROCESSES.

The quality and supply of iron will determine the method adopted for converting it into steel. It costs more to convert steel in the basic furnace, because repeated re-working is necessary. The acid process is easier to control, and there is greater certainty as to the composition of the steel. The acid furnaces would undoubtedly predominate if the larger part of the iron supply were low in phosphorus. But such is not the condition in the United States. Most of the low phosphorus iron is treated in bessemer converters, and the supply of bessemer ores is rapidly being exhausted. No new important discoveries are being made. High phosphorus iron is cheaper and more abundant, and there is an ever increasing supply of scrap which is unsuitable for the acid treatment. Thus the higher cost of the basic process is offset. As to the quality of the steel, it may be said that while the stock is superior to begin with and the product more even in the acid process, just as good, and even better steel may be made by the basic process. The danger of overheating while the heat is prolonged for the removal of phosphorus may be guarded against by proper management. The basic furnaces now greatly outnumber the acid.

Tungstic acid may be separated from silica by heating the material in a current of air and chloroform vapor to 500°C. The W is vaporized and passes off as a mixture of oxychlorides, which may be condensed in a suitable receiver.

CYANIDATION OF MANGANESE SILVER ORES.

By E. M. HAMILTON.

*When I first attempted to treat manganiferous silver ores I did not suspect an intimate association of the silver with the manganese, though I knew both were present. I tried cyanidation with all strengths of cyanide, even up to 5%, on samples of the ore ground to pass a 200-mesh screen, and could only extract 5 to 15% of the silver. I tried the addition of all kinds of reagents, such as lead-salts, oxidizers, chlorides, oxygenation with air, and hot solutions, without effect. I then started a course of reasoning somewhat as follows: I ascertained that this insoluble silver was contained principally in the surface-ore between the croppings and the 200-ft. level, while ore from the bottom of the mine would yield 90 to 95% of the silver without any trouble. The ore in each case appeared to be quite similar, except that the surface-rock which gave trouble was highly oxidized. Then it occurred to me that if I could reverse this condition and treat the oxidized ore with a reducing agent I might get a result similar to that obtained on the lower-level ore from the sulphide zone. I accordingly subjected the finely ground ore to treatment with solutions of various reducing agents, among which were hydrogen sulphide, sodium sulphide, sodium hydro-sulphide, ammonium hydro-sulphide, and roasting with sulphur in a closed vessel. The charges were agitated for about 24 hours and then well washed with water, and cyanided by agitation in bottles. The sodium sulphide had no effect whatever, but both the ammonium and sodium hydro-sulphides, and the hydrogen sulphide, increased the subsequent silver extraction to about 73, against about 5% by straight cyaniding. The cyanide consumption was also increased from about ½ lb. per ton in straight cyaniding to 12 lb. per ton for the samples treated by hydro-sulphide, and to 27 lb. for that treated by hydrogen sulphide. The resultant cyanide solutions carried large quantities of thiocyanate. The samples roasted with sulphur gave about the same yield as those treated with hydro-sulphide and about the same cyanide consumption. To try to reduce this heavy loss of cyanide the ore after reduction treatment was given various treatments before cyanidation, among which were the application of chlorine water and various chlorides and oxidizers, such as potassium permanganate and hydrogen peroxide, and also the blowing of air through the pulp. They were then well washed before cyanidation. In the case of the intermediate oxidation tests some cyanide was saved in the subsequent treatment, but the extraction of silver was considerably less than when the ore was cyanided immediately after the reduction treatment. The intermediate chlorine treatment made no difference in the cyanide consumption, but increased the silver extraction by 3 or 4 per cent.

Owing to the excessive cyanide consumption and the low value of the ore (\$8 to \$10 per ton) this method of treatment by reducing agents could not be entertained, although, if the cyanide loss had been

*Abstract from *Jour. Chem. Met. & Min. Soc. of S. A.*

normal, the method would have been well worth considering. The reason why this treatment increased the silver extraction was rather mysterious, and attempts were then made to ascertain the mode of occurrence of the silver. By grinding the ore to pass a 200-mesh screen, and boiling for an hour in strong nitric acid, then washing well with distilled water, and assaying the residue, the latter was still found to contain 75% of the original silver content. This residual silver, insoluble in nitric acid, could not have been in the metallic or sulphide forms, nor was it mechanically inaccessible in the ordinary sense, because a sample of the pure clay-slime from the ore was even more refractory to nitric acid than the general sample. It might have been in a haloid form, but in that event it should have been soluble in cyanide or sodium thio-sulphate, which reagents had practically no effect on it. At about this stage of the enquiry I obtained the assistance of G. H. Clevenger, who made many experiments, of which the following is a short summary: (1) bromo-cyanide, results rather inferior to those by straight treatment; (2) addition of zinc-dust as a reducing agent, no result; (3) addition of metallic sulphides with a view to breaking up any hypothetical haloid compounds, no result; (4) addition of strong alkali, with and preliminary to cyanide treatment, no result; (5) preliminary treatment by pan amalgamation, no result; (6) preliminary treatment with chlorine and bromine prior to cyaniding, no result; (7) preliminary roast before cyaniding, result—not a trace of silver soluble in cyanide; (8) preliminary chloridizing roast, result—fair silver extraction (75%); (9) concentration of the ore ground to 200 mesh, result—tailing assayed rather higher than concentrate; (10) oil-concentration, no result; (11) acid flotation, no result; (12) preliminary treatment with hydro-sulphides, results confirmed the tests made by myself, as described above; (13) preliminary treatment with hydrochloric acid, result—94% extraction of the silver. From the foregoing it appeared that the silver is in very intimate association with some other mineral, probably with the manganese, possibly occurring as a definite manganese-silver compound.

As to how the silver may be made amenable to cyanide solution, however, I have concluded that chloridizing is not the only, and probably not even the best, method. I am led to think that instead of trying to attack the silver, which is comparatively small in quantity, the aim should be to attack the predominant partner in the combination, that is, the manganese. In the above detailed tests, a chloridizing roast yielded only 75% of the silver on subsequent cyanidation, while the preliminary treatment with hydrochloric acid allowed of an extraction of 94%. Of course, in this latter instance, Mr. Linton may reply that the result was due to nascent chlorine formed by the manganese dioxide; it might, however, be equally well due merely to the dissolving action on the manganese, exposing the contained silver to the action of the subsequent solvent, and this view would seem to be strengthened by the fact of the chloridizing roast giving results so much inferior to those of hydrochloric acid. But if this latter view be correct, how are we to account for the re-

sults due to a preliminary reduction with hydro-sulphide? The only suggestion I have to offer is that the manganese being converted into sulphide became sufficiently soluble in the cyanide solution to expose most of the silver to the action of the solvent, forming thiocyanate and manganocyanide of potassium.

Working on the hypothesis of the necessity of finding some solvent that would break up the combination and free the silver, I tried a preliminary treatment with many reagents. (1) Nitric acid had been found useless in the early stages of the investigation, probably because it did not attack the manganese dioxide. (2) Hydrochloric acid, while very effectual, appeared to be prohibitive in cost. (3) Sulphuric acid was without effect. (4) The hydro-sulphide treatment, while effectual, was prohibitive on account of the loss of cyanide, though I found it possible to regenerate KCN from KCNS by electrolysis with caustic soda, and it might have been possible to recover some of the cyanide in this way. (5) Finally I tried 5% solution of sulphurous acid. After washing and cyaniding the residue I obtained an extraction of 84% of the silver with a cyanide consumption of only 4 lb. per ton of ore. This method seemed by far the most feasible of any, and if the ore had assayed a few dollars higher than it did the method would certainly have been tested on a working scale. The amount of sulphur required would in this instance have been about 100 lb. per ton of ore.

Thus it is seen from the foregoing results that there are several methods of treatment besides chloridizing which were found to give good cyaniding extractions on the silver in this manganiferous ore: (a) preliminary roasting with sulphur in absence of air; (b) preliminary treatment with alkaline sulphides; (c) preliminary treatment with hydrochloric acid (it may be open to those who think differently to put this method in the chloridizing class); (d) preliminary treatment with sulphurous acid. Of all these, the last seems the most practicable and least expensive, and with an ore assaying a little higher than that which was experimented on, would seem to offer a workable solution of the difficulty in the cyanidation of these manganese-silver ores. It may be remarked that the gold in such ores usually yields uniformly high extraction of about 90% under almost any circumstances regardless of the behavior of the silver.

Sulphides, polysulphides, and hyposulphites in the same solution may be determined as follows, according to Dhuique Mayer: dilute 10 c.c. of the solution to 100 c.c., and of this dilute 10 c.c. to 200 c.c., and titrate with N/10 H_2SO_4 with phenolphthalein indicator (A). Titrate this with N/10 I solution and starch indicator (I). Decolorize with a minute drop of the original solution, and titrate with N/10 NaOH (R). Dilute another 10 c.c. of the original, shake with 2 gm. $PbCO_3$, and titrate the filtrate with N/10 I (H).

A = Sulphides. R = total NaHS.

R - A = true NaHS. I - 2R = polysulphide and hyposulphite.

H = hyposulphite. (I - 2R) - H = polysulphide.

In the case of polysulphides divide the titer by 2 and calculate as Na_2S_2 .

GRAPHITE—AN OBSTACLE TO GOOD CYANIDING.

Written for the MINING AND SCIENTIFIC PRESS
By M. W. VON BERNEWITZ.

Graphite occurs in gold mines in different parts of the world; and in several instances it has proved to be a great nuisance in the treatment of ores by cyanide. In the treatment of the sulpho-telluride ores of Kalgoorlie, it was noticed in certain mills that the extraction occasionally fell off for no apparent reason, although all conditions were favorable for good work. Ore from certain parts of the mines was known to contain graphite, and it was when this class was being milled that the trouble occurred. In the mines on the eastern side of the 'Golden Mile', the Brownhill, Associated Northern, Oroya, and Associated, the three first named working solely on the well known Brownhill lode, and the latter partly on the south end of it, the graphite is found in the slate or schist in fair quantities. In the Brownhill it is not

Associated Northern Mine.

important in this connection. The graphite occurs generally on the hanging wall of the lode, but without doubt there are numerous seams through the lode itself. This appears from the fact that even if the hanging wall material is sorted out, a little graphite still comes to the mill. In the Associated Northern, pockets of almost pure graphite are sometimes found. The mineral also occurs on the walls of the lode in the Great Boulder mine, and in the Lancefield mine, some 200 miles north of Kalgoorlie.

When breaking down ore in the Associated Northern, the graphite can, to some degree, be picked out; but where it is finely distributed through the ore this cannot be done, and remains to complicate the subsequent treatment. In the dry-crushing mills, during the roasting of the ore no doubt some of the graphite is burnt, but the bulk remains unchanged. When the roasted ore is mixed with the circulating waters the trouble commences. The graphite forms a scum on the pulp in the grinding pans, collects on the overflow lip, and from here no doubt a great deal floats away with the slime to the settlers. Likely enough a little may go to the agitators with the thick slime, although as regards the latter point there is no proof. The circulating waters are weak KCN washes (about 0.04%) from the filter-presses, and contain from 50c.

per ton or more in gold. I think there is little doubt that a precipitation of the gold takes place while the graphite is in violent agitation with the pulp in the pans, and probably some precipitation in the settlers. As to its taking place in the agitators with 0.08% KCN, no means are available for determining. Extraction generally drops from 2 to 5% when graphite is present, varying with the grade being milled. Scum collected from the pans was filtered and washed carefully, and assayed. In the cupel a fair sized bead of gold was seen, but as the quantity assayed was small and there was nothing definite as to the amount of graphite in the ore, no calculation of its value was made. It seemed clear, however, that the graphite had precipitated this gold from the circulating solutions. The graphite schist from the mine gives only a trace by assay. It may be mentioned that there is a good deal of gold dissolved by the circulating solution in the pans and settlers, as well as in the agitators. An analysis of the graphite slate or schist is as follows:

| | Per cent. |
|--|-----------|
| Insoluble (silicious matter) | 86.80 |
| FeS, | 3.28 |
| Fe ₂ O ₃ | 4.53 |
| Al ₂ O ₃ | 1.40 |
| CaO | 1.40 |
| MgO | 0.25 |
| C (graphite) | 0.75 |
| H ₂ O, and undetermined | 1.59 |
| | 100.00 |

By increasing the final heating in the furnaces a good deal of the graphite would be destroyed, but such heat would sinter the ore, which is undesirable. A sample roasted in a muffle-furnace resulted in the graphite being burned off, but the conditions in a muffle and those of a roasting-furnace are entirely different. In roasting this sample the ore was well stirred, and when agitated with gold solution the extraction was all right. Other samples of ore, roasted, but not stirred much, and agitated with solution for 16 hours, showed poor results. It has been suggested, and tried, that the grinding should be done in fresh water, as the graphite would not have the same chance to precipitate any gold. This is all right, but it would require running to waste a good deal of spent solution every day, which would hardly pay, since the manager seldom knows when the graphite is coming into the mill. Being finely distributed in some classes of ore, its first appearance is on the pans. Solution accumulates in slime plants to an annoying degree at times, let alone taking in extra quantities. Using only barren solutions for the pans was tried for some time, but as mentioned above, a good deal of gold is dissolved in this department, and the graphite will do its work just the same.

To illustrate the different behavior of graphite and charcoal, I might mention that the ash-heap from the furnaces is being put through the mill at our plant. The ash is about equal parts of charcoal and dust, the latter from the hot-ore conveyor, hot air being taken here from the fire-box. During the roasting all the charcoal is burned out and no trouble is experienced. The waste acid from the clean-up is run through two large boxes of charcoal. When it

gets rich enough, say 20 oz. per ton, it is dried, fed into the ball-mills, and mixed with the ore. It is completely burned in the roasters and causes no after effects.

The Oroya-Brownhill, working the same lode as the Associated Northern, treats its ore by wet crushing with stamps, concentration, pans, and tube-mills, agitation with BrCN, and filter-pressing. Ore containing graphite is occasionally sent to the mill, and soon thereafter the extraction and even precipitation falls off. The graphite forms a scum on the settlers, the circulating waters being a weak KCN solution. At the Associated the ore is treated by the ordinary dry-crushing and roasting process, and although a little graphite finds its way into the mill, little trouble has been experienced from this source. The graphite shown me on the Great Boulder mine is a pure graphitic schist, and is found on the walls of the lode in places. The ore is treated by ball-milling, and Griffin mills and roasting, and the graphite gives trouble by precipitating the gold. At the Lancefield there is both graphite and arsenic in the ore, and the treatment of these has not yet been determined.

A custom mill here, the Kalgoorlie Gold Recovery Co., buys sulphide ores, concentrate, slags, etc., treating these products by ball-milling, roasting, grinding, and filter-pressing, as the case may be. Now and again old crucibles and the like are mixed with the charges, and the graphite from these floats on the top of the thick slime in the cone agitators, agitation being effected by air at 10-lb. pressure. So far, the manager has not been able to see that bad results are caused by the graphite; but a strange thing was noticed, that, in filling 5 cones with the same class of slime, the graphite would only form a scum on one. We have noticed the same occurrence with the pulp in our pans.

The matter rests at that, and until some method is devised to deal with the graphite, the trouble can only be minimized by carefully excluding such ore from being sent to the mills.

Portland cement analysis, according to Dementieff, may be accurately made as follows: the cement must be pulverized exceedingly fine, and then on digestion with diluted HCl, SiO_2 and all can be brought into solution. If the HCl is of known strength some constituents can be determined by titrating back with normal NaOH. Without adding an indicator run in normal NaOH until the solution clouds. This indicates the amount of excess of HCl used. Add phenolphthalien and then run in N/NaOH to coloration; this gives $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ (filter off and determine Fe_2O_3 in the precipitate by the usual method—reduction and permanganate titration). On heating the clear solution the phenolphthalien coloration slowly disappears; continue adding the NaOH until the color is permanent while hot; the amount of NaOH so used, when doubled, corresponds to the MgO present. The reaction is explained by the author as due to the gradual formation of $3\text{MgO} \cdot \text{SiO}_2$ which separates on heating. Under these conditions where there is not sufficient SiO_2 to combine with both CaO and MgO, the latter combines preferably with the SiO_2 .

COSTS AT THE BRADEN COPPER MINE.

By WILLIAM R. BRADEN.

*The following is an extract from the operating report of the Braden Copper Co. for November 1908. Costs are given in United States currency, and weights in dry tons of 2000 lb. The total cost of breaking 16,185 tons, including superintendence and general charges, was 41c. per ton. Upon the basis of 7304 tons extracted and milled, the costs per ton were distributed as follows:

| | |
|-------------------------------------|--------|
| Ore breaking | \$0.31 |
| General mine expense..... | 0.06 |
| Development | 0.12 |
| Underground tramming | 0.02 |
| Aerial tramming | 0.06 |
| Milling: Operation | 0.27 |
| Repairs (labor) | 0.01 |
| Repairs (materials) | 0.09 |
| General mill expense..... | 0.05 |
| Power | 0.01 |
| Sampling and assaying..... | 0.05 |
| General expense | 0.23 |
| Taxes, insurance, and interest..... | 0.04 |
| | <hr/> |
| | \$1.32 |

The ore-breaking account includes much cutting out for ore pockets, sub-cross-cuts, raises, and other work of a preparatory nature. More than one half of the labor was performed by contract. In the stopes, contracts were let on the basis of the number of feet of hole drilled. The actual cost of the labor for one month was: 164 man-days (9 hr.), with $2\frac{3}{4}$ -in. New Ingersoll air-drills, drilled 5082 ft. at a cost of 2.025c. per foot. Average amount drilled per man-day, 31 ft.; 1008 man-days, by single hand work, drilled 13,855 ft. at a cost of 8.2c. per foot. Average amount drilled per man per day, 13.8 ft. Including all labor, both contractors and day pay men employed for mining, there were 12 tons of ore broken per man-day. Since the above date, a system of contracting for ore-breaking by measurement of the ore broken has resulted in a considerable reduction of the cost for that item in the foregoing statement.

Development included drifts, cross-cuts, and raises, with an average section of 4.53 sq. m., and, including all labor, supplies, explosives, mucking, and tramming, the cost was \$3.54 per foot driven, or 78c. per cu. m. The amount of driving was 379 linear feet, with 876.75 man-days, making 13 linear feet per month per man, or 0.433 ft. per day, and 1.96 cubic metres.

A concrete idea of what is considered to be good work is illustrated by the case of a contract let for driving a main adit, of a section of 6 sq. m., at a total cost of \$3.15 per running foot, exclusive of drill sharpening and repairs; 132.25 ft. were driven in 30 days. Payment of all labor accounts is made three times in each year, on January 1, May 1, and September 1. The workmen are permitted, however, to draw up to 80% of their balances at any given time; a custom of the country which leads to constancy of work and gives entire satisfaction. Wherever possible, a bonus is paid to encourage good steady work.

*Abstract from paper read before Amer. Inst. Min. Eng., Spokane meeting.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

All-Sliming.

The Editor:

Sir—I have read with very great interest E. M. Hamilton's article on 'All-Sliming', which appeared in your issue of August 21. In it Mr. Hamilton describes a method devised by him for the separation and collection of fine sand for cyanide leaching. A practically identical method of classification has been in use at this mine for the past twelve months. It was thought out by George L. Carlisle, a local mine operator, and has given entire satisfaction, producing the cleanest product it has been my fortune to handle; this with a mill product averaging over 60% slime.

After passing through a cone classifier, which removes the lighter slime, the battery product is fed to a distributor possessing arms of such length that the pulp is directed against the sides of the vat. All the arms are of equal length and have nozzles bent at an angle of 45°, exactly as described by Mr. Hamilton. The pulp running down the sides of the vat builds itself gradually upward with a smooth level floor sloping gently toward the central discharge. This discharge consists of a vertical wooden tube of square cross-section, 3 in. diam. On two sides are bored 2-in. plug-holes at 4-in. centres. These are staggered in such a manner that there is a hole for every 2 inches in height of the collecting tank. The slime running down the sloping surface

of the collected sand, is discharged through the holes. As the tank fills, the sand gradually approaches the centre, and when within 18 in. or thereabout of the plug-hole, the latter is closed with a wooden plug, and the slime-discharge takes place through the aperture next above.

It will be seen that this method only differs from that of Mr. Hamilton in the form of the central discharge. His method, that of a tube built up in sectional rings as the tank fills, has the merit of obviating descent into the tank. At this mine a ladder is left in the collecting vat as it fills, standing on the rungs of which the workman puts in the plugs as occasion requires. The method of filling with a Butters distributor, meanwhile drawing off the slime through plug-holes, is not new, having been used in at least one Californian plant. There, I believe, the holes were in the periphery of the vat. The use, however, of a distributor having arms of equal length so arranged as to allow the pulp to impinge on the wall of the vat, coupled with a 'built-up' central discharge, seems to me to be original with Mr. Hamilton and Mr. Carlisle, and a happy instance of two minds in different parts of the world hitting upon the same ingenious and simple idea.

Time-Sheet Voucher.

The Editor:

Sir—Below is a time-sheet voucher form which we have found valuable in our work and which may be of service to others as a base for their own.

We have these punched, and when a man comes to work for us we enter on one of these sheets his name, amount of wages, and where he is working. It is

[Specimen Copy.]

TIME SHEET VOUCHER.

THE ARIZONA HERCULES COPPER COMPANY.

Name, Martin Navarro.

Time sheet for month of October 1909.

Where working, intake for pipe-line.

Wages per day, \$2.

Balance, sixteen and 60/100..... \$16.65

Approved, W. P. DUNHAM, President.
E. G. THOMAS, Secretary.

Received in full payment of the above account from the
his
Arizona Hercules Copper Co., MARTIN X NAVARRO.
mark

Ray, Arizona, November 10, 1909.

The above has been examined and found correct, E. G. THOMAS, Superintendent.

then hung up on a clip having a pasteboard flap marked 'Time Sheet Vouchers'. When our men come for orders on the stores, or when a debit, or any account is charged against one, the entry is made in the appropriate place. At the end of the month, or when the man leaves the service of the company, the time-sheet, signed by him, forms a voucher. It is printed on paper $7\frac{1}{4}$ by 9 in., which can be folded conveniently for filing. On the back is an ordinary voucher record form.

W. P. DUNHAM.

Ray, Arizona, November 15.

Modern Quicksilver Reduction.

The Editor:

Sir—I note with interest the criticism by H. W. Turner of Mr. Strauss' article on the reduction of quicksilver ores. The point, that mercurial soot does not accumulate in the furnace, is well taken, but I think Mr. Turner's further statement that, "in American furnaces 70% of the mercury runs out of the condensers as pure metal," is true only exceptionally. The grade of the ore governs the yield more than almost anything else. This is due to the fact that the fuel gases, passing through the condensers, are practically constant; while the mercurial, sulphurous, and other gases emanating from the ore vary with the grade of the ore. Consequently, the proportion of the soot condensed from the fuel gas does not increase with increase in mercury, and as the mercury portion of the soot increases sufficiently it drops on the inclined condenser floor and accumulates into puddles which have sufficient gravity to force their way through the soot down to the channel. The amount of free metal is also governed by the character of the ore. In Texas, where the mineral occurs in limestone, there is practically no difficulty in condensing, and the percentage of free metal is high; but in Arizona and Mexico, where the mineral occurs in schist and is free from all lime or iron, proper condensing is more difficult, and there is practically no free metal. In Texas, with 0.5% ore, the free metal was 15%, while with 1% ore, the free metal amounted to 46% and the free metal increases as the grade of ore increases. As to the loss in reducing quicksilver ores, I do not know of a plant in America which is properly equipped to determine the absolute loss in roasting quicksilver and condensing the fumes therefrom. I have read many guesses as to what this loss amounts to, varying from 4 to 25%, but no one has offered evidence to substantiate any of these assumptions. As for myself, when a plant has been in operation some time, and the condenser bricks thoroughly saturated, I would guess about 5%. Of one point I am satisfied—the loss does not occur through inefficiency in the roasting plant. A well built furnace of the Scott type, properly conducted, will volatilize practically all the metal in an ore, provided the ore does not exceed 2.5%, but the brick condensers connected with this same plant are about as poor condensers as it is possible to have, and they are accountable for most of the loss in the reduction of quicksilver ore.

CLIFFORD G. DENNIS.

On the train, November 20.

American Merchant Marine.

The Editor:

Sir—In the days preceding the Civil War the United States is said to have been the leading maritime nation of the world. It is also said that the shipping interest was built up by discriminating in tariff duties between American and foreign ships, by giving those sailing under the American flag lower duties than were given to foreign ships. If that policy made this the leading maritime nation, why should it not do so again?

W. C. WYNKOOP.

San Francisco, November 20.

[One of the early acts of the Federal Congress after the adoption of the Constitution was to encourage American shipping by granting a rebate of 10% upon customs duties on goods imported in American bottoms. The stimulus of this law called into being a merchant marine which excited the hostility of Great Britain. The fixed policy of that country since the days of Drake has been to prevent the growth of any rival merchant marine. This led to the development of a great navy, and to activity in naval warfare which has made Great Britain the dominant sea-power of the world. Only recently has a rival been suffered to develop serious strength upon the seas, and that has been the cause of some embarrassing interpellation of Mr. Asquith on the floor of the House of Commons by gentlemen in opposition. The development of American shipping during the early days of the Republic has been ascribed by some to the superior timber available for that purpose along the New England coast, to the greater cheapness of naval construction in America at that time, and to a reputed superiority of American seamen. It was evident that British statesmen entertained no fantastic notions in regard to these supposed advantages. The development of the American merchant marine, unattended by an equivalent fighting navy for its protection, led to the war of 1812, resulting in what might be termed a drawn game, from which Albert Gallatin's astuteness as a diplomat, aided by Henry Clay's dogged persistence won for the United States more treaty benefits than the relative military and naval positions of the parties at the end of the struggle would have strictly warranted. But the treaty of Ghent left open other questions, to be settled by a commercial treaty later on, and it was in the subsequent adjustment of these commercial matters that America lost her position as an important maritime nation. In compliance with the commercial convention and agreements between the two countries, the law providing for discriminating duties was erased from the statutes by Act of Congress in 1828. The decline of the American merchant marine from that time forward would plot a rapidly descending curve, which argues ill for the theory of natural advantages which this country was supposed to enjoy. At the present time the advantages in cost of construction favor the foreigner because of our tariff. To re-establish an act for discriminating duties, some exceedingly delicate work would be required of Mr. Knox to negotiate treaties releasing us from the engagements made at a period of national weakness.—EDITOR.]

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Mining claims in Honduras are taxed ₡10 per pertenencia of one hectare, when the denouncement has been for gold and silver, and ₡5 for coal, salt, and other substances. The taxes are due and payable in January of each year. Failure to make prompt payment causes the loss of the property.

Carbon, while an almost perfectly resistant converter lining in steel making, is rapidly destroyed on account of the affinity for it of that metal. It has often been tried in the form of brick, as well as rammed with tar, and although the matter is again under review its practical use seems out of the question.

Electrolysis of very active metals like manganese and silicon, when using alternating current, results in the solution of these metals, that is, one half wave dissolves, but the other does not re-deposit. Especially inert metals like platinum are deposited by alternating currents, the negative half wave depositing, but the positive half wave does not dissolve.

Phonolite is the volcanic equivalent of nepheline-syenite, and consequently is rich in soda. It may be described as nepheline-trachyte. The phonolites are porphyritic rocks with a completely crystalline matrix consisting of sanidine and nepheline in which occur isolated crystals of orthoclase, nepheline, and pyroxene. Phonolites are readily decomposed.

Desecho is used in many senses in connection with mining in Mexico. In the patio process it is applied to the floured mercury. It also means the waste material rejected in the sorting of ores; and the waste rock produced in mining is similarly called. It is also a name given to the gob-walls, in the building of which the Mexicans are particularly expert. The refuse or skimmings from lead refining are also called *desechos*.

Vanning is a name given originally to the testing of an ore by concentration on the point of a shovel, after the manner of washing in a horn-spoon. It gives a particularly clean concentrate in the hands of a skilled operator, and makes a high saving of the heavy minerals contained. Vanners attempt to imitate the same motion, but it is extremely difficult to accomplish it mechanically. Recent forms of vanners have an oscillating motion instead of a simple side-shake, but this still misses the ideal vanning movement.

Machinery and other improvements which are affixed to the land are real property and become the property of one who makes a valid re-location of the ground on which they are situated. A sale of such improvements by the former owner prior to forfeiture would not affect the rule as to fixtures, unless they are removed before adverse rights attach. In cases of mistake and fraud, however, courts have sometimes interposed and exercised their equitable powers and allowed the original owner to re-

move fixtures. The fact that the re-locator is a stockholder in a company which formerly owned the ground would not of itself affect his right to make a re-location of the ground, provided there is no bad faith involved, and provided he does not hold a fiduciary position in the company.

Regenerators were formerly placed under the open-hearth furnaces which they served. Old furnace men still claim that with such construction a furnace works somewhat quicker than does the present type. The objections are: (1) When the furnace rests on the arches of the chambers there is always some distortion due to changes in temperature and it is difficult to keep the structure gas and air tight. (2) Any breakout allows the metal from the hearth to run directly into the checkers, filling them and making an enormous amount of work before the furnace can be again put in commission. (3) Repairs are more difficult to make.

Alaskite is a term proposed by J. E. Spurr to designate the group of holocrystalline quartz and alkali-feldspar rocks to which the name aplite had previously been rather loosely applied. Aplite had come into wide use as a textural term applied to rocks of many kinds usually occurring as dikes. Rocks of granitic texture and habit, consisting essentially of quartz with orthoclase or other alkali-feldspar are wide spread in Nevada and the term alaskite has found ready acceptance in discussions of the geology of that State as well as in Alaska where it was first applied. With addition of black mica, alaskite grades into biotite-granite.

Matte is an artificial sulphide formed in smelting as a result of the union of sulphur with bases. Iron sulphide such as is used in making hydrogen sulphide in the laboratory is the simplest form. To produce it in small quantities an assay crucible may be filled with nails and brought to a white heat, sulphur being added until the content fuses. In smelting a charge containing sulphur, scrap iron will take up the sulphur and form matte. If copper oxide or copper sulphide is present the sulphur unites with the copper in preference to the iron. When the copper is exhausted, the excess of sulphur expends any remaining combining power in taking up iron.

Vanning shovels as made in Cornwall consist of thin sheet-iron plates weighing 2 to 3 lb. The plate is 14 to 15 in. long by 13 in. wide, and is dished nearly an inch in the centre. It has a socket or eye to receive a handle and the back of the shovel on either side of the eye is slightly turned up. The handle, which is about 3 ft. long, is usually of ash or hickory, and has a bend a little way from the socket. The face of the shovel should be smooth and kept bright. In the hands of a skilled vanner the separation of mineral from gangue is easy. The sample to be vanned is crushed ordinarily to 30 mesh. If the mineral is finely disseminated it may be necessary to crush to 60 mesh. The vanning shovel is used principally in determining the percentage of tin oxide present in ores. With care and practice fairly accurate concentrations may be made.

*Loss.

The diamond-drill at 2600 ft., in the Great Boulder, cut the lode on the Horseshoe boundary, there being 4 ft. worth \$7.25 per ton in the latter property. At about 600 to 800 ft. from the surface the two mines had the lode on the boundary, where it was very rich indeed. No doubt the Horseshoe will now sink to 2600 ft. from its present depth of 2000 ft. September was a very windy month here, and the dust from the dumps was really unbearable for work. The dumps being so high, the wind simply makes sport of them, and the dust flies for miles. Two mines have abandoned the stacking of residue by belt; one is now sluicing it away, and the other has reverted to trucking. This is just as cheap, and stops the dust nuisance. It was thought a fine plan a few years ago to use belt-conveyors for the disposal of residue, but ideas have changed of late. The Hannans Star and Boulder Deep Levels, on the south end of the belt, have amalgamated, amid much protest from local shareholders. The mines come in on equal terms which has been the subject of unfavorable comment. Despite this, the English shareholders have carried the business through. The Hannans Star has a plant of two Krupp ball-mills, a large tube-mill, settlers, agitators, and filter-press plant using the BrCN process. The plant did much custom work some years ago. In connection with the tube-mill, it may be mentioned that it was the first used in the world in the fine grinding of gold-bearing ores. I think this is a recognized fact, despite other claimants.

The erection of small suction gas plants continues, much rivalry between the different makers resulting. One make is rather well known on account of its crank shafts breaking. Up to 50 hp. gas plants do well. One of 37 hp. driving three Huntington mills which crush 100 tons of oxidized ore per day, and also furnishing power for several pumps, costs \$5 per day on charcoal, against \$30 using firewood for steaming. The erection of these plants means a difference to electric power plants, including the power company. With reference to the latter plant, it might be stated that, there are three vertical engines of 800 hp. each; and two horizontal engines, one of 800 hp., and the other of 1500 hp. driving generators direct. The vertical engines have the Corliss valve gear, but were never entirely satisfactory as regards steam consumption, so it was decided to remodel the engines with Sulzer valve gear. English and European engineers' suggestions were not satisfactory, so it was left to the firm of Kelly & Lewis, in Melbourne, to do the work. One engine has been altered, and is running satisfactorily

with more than 10% economy over previous operation. It may be explained that this was no easy problem to solve.

There have been good rains at Tawarin, the new gold field near the border of Western Australia, and the northern territory. At Southern Cross, some 100 miles west from here, is the Transvaal mine, with a good surface showing of ore worth \$15 per ton. The ore, however, is refractory as it contains about 15% arsenic. After much experimenting it has been decided to erect Krupp ball-mills, Edwards roasters, and the usual treatment plant. It will be interesting if this process is satisfactory, as the treatment of arsenical pyrite is no easy matter. In this connection, word comes from New South Wales that an oxy-hydro process has been successfully used on an arsenical ore over there. Details are not yet to hand. There has been more trouble with the firewood employees, but it is all but settled now. The government is to further tax dividend-paying mines. At the time of paying dividends, it is usual to pay the 5% duty. Now, however, the government requires payment on both the dividend and duty paid, being in fact, a tax on a tax. A test case is to be fought in the courts. The report of the engineers for the Transcontinental Railroad is now before the Federal House. It is most interesting, and contains data as to gauge, grades, water supply, pastoral country, desert, geology, and mileage. The cost is estimated at some \$20,000,000.

JOHANNESBURG, TRANSVAAL.

Bold Prospecting — Average Working Costs. — Driving on Lines.— Robinson Enlarged Mill.—Randfontein Progress.— Big Ore Reserves.—Acute Labor Shortages.

The boring operations of the New Rand, Ltd., undertaken to prospect for the Main Reef series below the Karroo beds (700 ft. thick), near the southern rim of the Wit-

Hand-Drill Work on the Rand.

watersrand basin, do not excite much local interest. The concern is financed in England. Full reports on the year's operations have appeared, written by A. R. Sawyer, the consulting engineer and leading spirit in the enterprise. For plucky and pertinacious effort, this probing in the dark by the New Rand is almost unequalled. Funds seem to come in satisfactorily, though the concern is not rich. Over 16,000 ft. of diamond-drilling has already been done, and, of course, it is always the next thousand that will reveal the 'New Rand'—a title which must inevitably prejudice Transvaal engineers against the company. Supposing cer-

tain beds can be roughly correlated with known markers on the Rand, there is no reason to assume that the Main Reef horizon can be accurately determined, or, if a strong 'banket' series is cut at a likely horizon, that there will be payable gold. There are ample exposures of Witwatersrand formation, with numerous 'banket' beds at Venterskroon to the west of the New Rand's area, and in many places stretches of payable ore occur. But no geological authority has presumed to mark the Main Reef horizon. If, then, we are in the dark as to precise correlations in a great outcropping succession of beds of Rand formation, how is it that such confidence can be expressed in determining horizons and the identity of indicators by means of bore-hole cores? If Mr. Sawyer cuts a payable reef, it will provide some hope of subsequently successful mining; but let the 'Main Reef' and 'New Rand' word-juggling be dropped.

Rand working costs appear to have reached a temporary halting place, in their downward course, at about 17s per ton. The shortage of native labor, resulting in reduced tonnages and an increase of machine stoping, has no doubt been one of the causes militating against the continuance of the gradual reduction. Although the average costs of \$4.08 per ton milled have been published far and wide, an analysis of the items has not lately appeared. Averaging the figures for a large number of representative mines, the following segregation may be obtained and presented as typical of the Rand today:

| | Per ton mined. | Per ton milled. |
|---------------------------------|-------------------|--------------------|
| Mining. | | |
| Stoping | \$1.04 | \$1.20 |
| Shoveling and tramming..... | 0.42 | 0.48 |
| Pumping, hoisting, etc..... | 0.48 | 0.56 |
| | \$1.94 | \$2.24 |
| Sorting | | 0.06 |
| Crushing | | 0.05 |
| Transportation | | 0.06 |
| Stamp-milling | | 0.37 |
| Tube-milling | | 0.14 |
| Cyaniding, sand | | 0.28 |
| Cyaniding, slime | | 0.12 |
| General and head office..... | | 0.32 |
| Total, except development | | \$3.64 |
| Development | | 0.42 |
| Grand total | | \$4.06 |

The percentage of sorting averages 15.5, and the yield per ton milled, \$6.70, giving a net profit, after allowance of 8 to 10% for profits tax or about \$2.40 per ton.

In a recent letter it was mentioned that the Rand Collieries, Ltd. (a gold mine in faulted portion of the East Rand), proposed to run their levels straight, instead of following the 'reef'. In the last quarterly report it is stated: "The levels are now being driven on line under the reef, with the exception of the connecting drive to No. 2 shafts, and therefore no reliable data can be given of current development." Is this good policy? The Rand Collieries and the adjacent Van Dyk have not made as good a showing in development results as at one time anticipated. Few properties on the Rand have more urgent need to 'hug' the reef, and thus gain as much knowledge of grade and faultings as possible. The time is not yet ripe to think of economical haulages and so forth. The Robinson, which has stood at the head of the list of single-mill producers for nearly two years, is about to drop an additional 40 stamps. At present it is running 210 heads and four tube-mills, the tonnage being about 47,000 per month, and a yield of £110,000. When dropping 250 stamps, the yield will not increase proportionately, for the new plant was primarily erected to deal with Main Reef, which only averages 20s. per ton, as compared with the present average

for ore from all sources of 45s. Running at full pressure, the enlarged mill and cyanide works of the Robinson will be producing gold at the rate of £1,400,000 per annum, from a block of ground 190 acres in extent which has been mined steadily since 1888. The Randfontein group, controlled (in every sense of the word) by Sir J. B. Robinson, is so frequently the basis for idle rumors and so much secrecy is allowed to enshroud its operations, that we must be grateful to the *South African Mining Journal* for publishing photographs of the construction work in hand on the Central mine. It is now certain that the erection of the great 600-head mill under one roof, is going ahead rapidly. The concrete foundations, in two rows each 607 ft. long, 12 ft. high, and 10 ft. wide at the base, are completed. The Nourse Mines, Ltd., (a subsidiary of the Rand Mines, Ltd.), appears, from its recently issued annual report, to be in a remarkably strong ore reserve position, as, indeed, are the majority of the Eckstein mines. This company has lately been milling at the rate of 500,000 tons per annum, but increase of plant will soon raise it to 700,000 tons. The ore reserves are calculated at 2,100,910 tons of payable ore (7.1 dwt.), and 750,000 tons of unpayable (3.2 dwt.), equivalent to a good three-years supply. The labor shortage, influencing nearly all the mines of the Rand adversely, is most acutely felt by certain recently equipped mines which are unable to expand from the developing to the producing stage. Thus, the Vogelstruis Consolidated Deep is unable to operate its new mill, and the Geduld, which has already done some experimental milling, is unable to resume. A number of mines are running on short time or with stamps hung up. Those companies whose nominal labor complements are fixed on a hand-labor basis, and which can probably employ machines economically for a portion of their tonnage, are best able to face present difficulties.

BRITISH COLUMBIA.

Greenwood Smelter. — Granby Mines at Phoenix. — Copper Costs.

The British Columbia Copper Co., at Greenwood, is mining and smelting 1800 tons of ore per day, having three copper furnaces in operation. This company's fiscal year ends November 30, and the official report of the year's operations, by J. E. McAllister, general manager, will soon be published. It is generally reported in this district that the B. C. Copper company has acquired control of the stock of the New Dominion Copper Co., and that the mines of the latter will be operated in close association with those of the former company. The New Dominion mines include the

Map of Part of British Columbia.

Brooklyn, Standard, Stemwinder, Idaho, and Rawhide, in the neighborhood of the Granby; the Mountain Rose, at Sunset camp, the Athalston at Wellington, and the Sunset and C. O. D. at Deadwood, near Greenwood. Some prospecting by diamond-drills is in progress on its properties

at Phoenix, and it is believed a considerable force will be put at work within a few weeks.

The Granby Mining, Smelting & Power Co. is mining about 4200 tons of ore per day at its Phoenix mines, with a force of 550 men and 70 air-drills. At the Granby mines proper, there are three shipping units, comprising adits No. 2 and No. 3, and the Victoria shaft. No. 2 adit, which goes in 1800 ft., has steam locomotive haulage, but equipment for electric haulage has been ordered and will soon be installed; No. 3 adit, which has been driven in the same distance as No. 2, is already equipped for electric haulage, all the ore broken between No. 2 and No. 3 being handled from this level. In moving the ore from these levels to the railroad shipping bins 10-ton cars are used. In the vicinity of these two adits is No. 2 shaft, 400 ft. deep, used exclusively as a manway and for carrying steel to and from the workings. The Victoria shaft extends 500 ft. at a 60° incline, having three compartments, two for 7-ton skips, and one for a manway. The hoisting is performed by a double-reel 250-hp. Westinghouse electric hoist. At each of the shipping units named is a crusher that reduces to a fairly uniform size the ore before it is shipped to the smelting plant at Grand Forks. This company is also shipping ore from the Gold Drop mine, through its Curlew tunnel. The system of mine trackage of 30-lb. steel rails aggregates six miles in length. The cost of mining, transporting, and smelting Granby ores is said to approximate \$2.50 per ton. The cost of producing copper and putting it on board cars at Grand Forks is 7.12c. per lb.; with the expenses of transportation, refining, and marketing the product in New York added, the cost amounts to 8.8c. per lb. The recovery of copper from the ore approximates 20.3 lb. per ton, and the gold and silver extracted amounts to about \$1 per ton. The smelting plant treated 107,000 tons for October, and for November it handled about 130,000 tons. Assuming that the Granby company can mine and smelt an average of 4500 tons of ore per day during the next 12 months, its production for that period will aggregate 40,000,000 lb. of copper. This company has \$1,100,000 invested in the Crow's Nest Coal Co., which owns 40,000 acres of coal land in eastern British Columbia.

JOPLIN, MISSOURI.

New Mills and Mines at Duenweg, Sarcxie, and Elsewhere. — New Form of Lease. — Lawrence County Mines. — Oklahoma Deposits.

The zinc mines are beginning to feel the effects of returning prosperity. New mills are being built, old ones overhauled, and preparations are everywhere being made for active work. At Duenweg a new mill owned by the Wolfsheart company is almost completed. As soon as the pumps can drain the ground the plant will be started. The mill has a capacity of 300 tons. Development on this lease has been carried forward steadily during the panic season, and the ground is now well opened. It shows a sheet deposit similar to those on the majority of tracts in that camp. A mill is also being erected on the Deerstone land, at Neck City, by the Clifford company. It has a capacity of 150 tons. Rich deposits have been found on this land. The Smithfield mill, north of Webb City, is nearly completed. It is a plant of 250 tons re-erected. The Cameron property at Sarcxie, where a new mill was built last year, has been taken over by J. W. Boyd, the owner of the land. The lease is being put in condition for steady operation. The Cameron company has never given adequate attention to the property because of other interests in the East. This property is considered to be one of the best in that camp. The shaft will be sunk to lower levels at once. The old Kathleen property, in Lehigh valley, is being unwatered preparatory to re-starting. A new 150-ton mill is to be erected here. The ground shows free ore running 10% zinc. Two new shafts are being sunk in the Duenweg district by the Coahuilla company. One is in ore and the other almost to the ore-level. The property shows an unusually rich sheet ore deposit and no timbering is required. During its short operation the Coahuilla has been a heavy producer of zinc blende.

An interesting side light on how the future is coming

to be taken into account is shown by the plotting of a 20-acre tract in the Prosperity camp by D. Haughton with sub-leases subject to the provision that mining is to be confined to levels above 130 ft. This allows mining only in the soft ore deposits, leaving the sheet levels to future development. The property has been mined at shallow levels and much good galena removed. The old time free ore continues to be found on the Davey land, northeast of Joplin. Such ore has been recently developed on the Helen-Ruth lease, and on the May-Allen ground. Six holes have been put down on the Helen-Ruth, five of which cut ore. On the May-Allen eight holes have been sunk, four of which struck free ore, while the other four entered sheet zinc. The free ore extends from 130 to 150 ft. in depth. Much gouging for shallow lead has been done on this ground in the past, and one of the old shafts has been re-cribbed and sub-leased.

At Aurora and outlying camps in Lawrence county work is also active. Preparations are being made by Jim Housewright to re-open the old Daisy Bell mine at Aurora. A

Building a New Mill at Joplin.

recent accident here cost several lives. There is still much rich ore in sight and the mine will be entered through the shaft of the White Rose. The Industrial Mining Co. has just been organized in Aurora for the development of a tract of 200 by 930 ft. including the site of the old foundry. It is a part of the old Elliot property famous for galena. The company has let a contract for the sinking of eight shafts. On an adjoining tract a company took out \$40,000 worth of galena ore on a 100-ft. lot, the largest output ever made from a shallow mine in Aurora.

In Oklahoma, as well as Missouri, zinc mining is active. A discovery recently made by the Okmulgee Mining Co., at Miami, has made the property a producer. With a small two-jig mill the company is turning out a ton of zinc concentrate per hour, and a ton of galena per shift. The equipment is inadequate and fully 50% of the ore goes into the waste. Arrangements have been made for the erection of a large 200-ton plant on the Amalgamated Lead & Zinc Co.'s lease on a 10-acre lease of the Miami Royalty Co.'s land. Four shafts have been put down, three of them penetrating the rich run of ore opened on the Turkey Flat and King Jack adjoining. The ground is said to run about 25% ore, with the proportion of zinc blende to galena as 2 to 1. The ore extends in the shaft from 100 to 120 ft. Two rougher jigs are to be installed, the tailing from the first being sent over the second to insure a greater saving. The development in the Peoria camp has begun to attract con-

siderable attention, and a steady turn-in is now made weekly. E. E. Gordon, who is operating on the Keller lease, is just sinking a second shaft in order to save the long haul required underground since the extension of the drifts. The silicate is quite general, the grade being high, running 48%. On another lease operated by Mr. Gordon, a shaft is also being opened and the whole property revived after a long idleness due to litigation. The ore is mainly silicate though a small amount of blende is also produced.

LONDON.

Mount Lyell Report. — Definition of Mineral — Litigation.

An abstract of the report of the Mount Lyell Mining & Railway Co., for the half-year ended September 30, has been issued by cable. The total amount of ore smelted during the six months was 190,482 tons, averaging 2.81% copper, 1.98 oz. silver, and 0.6 dwt. gold per ton; of this 124,843 tons came from the Mount Lyell mine and 65,639 tons from the North Mount Lyell; in addition 499 tons of metal-bearing fluxes and 156 tons of purchased ore were treated. The yield was 4538 tons of blister copper containing 4484 tons of copper, 362,001 oz. silver, and 6489 oz. gold. In addition to the ore smelted, 6922 tons were used in the manufacture of acid. At the beginning of the six months 1088 tons of copper remained unsold. This has since been sold at an average price of £58 11s. 8d. Of the copper produced during the six months 3189 tons have been sold at an average price of £60 4s. 4d., leaving 1295 tons unsold in September. The net profit for the half-year was £139,850 after allowing £5299 for taxes, £9930 for depreciation, and £18,461 for exploration, and the dividend distributed absorbed £105,000. The amount of ore treated during the half-year was rather less than usual, a decrease accounted for by the interference of the weather with work in the open-cut. Extensive prospecting work has been conducted in the North Mount Lyell, and the most important development has been the discovery of bornite in payable quantities at the 1100-ft. level. The extent of the formation has not yet been fully ascertained, but the indications are encouraging. In the higher levels, notably those at the 700-ft., 850-ft., and 1000-ft., the orebodies have been found to be of greater extent than originally estimated, and the reserves have been correspondingly increased. The ore reserves on September 30 are reported as follows: Mount Lyell, available by open-cut 493,232 tons averaging 0.6% copper, 1.97 oz. silver, and 0.5 dwt. gold; at the North Mount Lyell, 777,594 tons averaging 6% copper, 1.33 oz. silver, and 0.1 dwt. gold. The reserves at North are 63,658 tons greater than six months ago, and are, in fact, larger than at any previous period in the history of the mine. The cost of producing blister copper was 15s. 5½d. per ton of ore as compared with 15s. 7½d. per ton during the previous half-year. With regard to prospecting work at other mines, it is reported that the properties on the Norfolk range, though proved to contain copper, are too far from communication to warrant development at present. Prospecting is also being conducted in the Mount Balfour district. The fertilizer works belonging to the company, at Yarraville and Port Adelaide, are in full operation, and the demand for the fertilizers is so strong in various parts of Australia that a new plant is being erected at Fremantle, Western Australia. This branch of the company's business has been a great success, and in order to cope with the extra work involved it will be necessary to appoint a special committee of the board.

Disputes continue in England relating to the definition of the word 'mineral'. The owners of mineral rights are always litigating with owners of surface rights and claiming the mineral values of deposits on the surface. Most of the cases are between railways and mine or quarry owners, but we also find the owners of clay beds making claims, and often these are allowed. The question arose recently in Parliament when the new taxes on minerals were proposed. In all cases it has been supposed that a mineral according to the Acts was any constituent of the earth's crust which gave an additional value to the surface, agricultural, or building value of the land. There has been a variety of judgments in the courts, not all in harmony, but on the

whole favoring the mineral rights. A decision of the House of Lords this week, however, has practically knocked over the whole of the arguments and given the benefit of the doubt to the landowner. The case was a dispute between the North British Railway and the Budhill Colliery Co. as to the right of the latter to quarry sandstone underneath the railway. The first two courts in Scotland gave the colliery judgment, but the House of Lords has unanimously reversed the decision and gone in favor of the railway. They went back to first principles and ruled that the Acts could never have meant to deprive a railway of the bed-rock on which it was built, although the stone might be of value for building purposes, and consequently be worth quarrying. This decision is quite subversive of many preconceived and old-fashioned notions, and will considerably alter the views of the subject in the future.

The litigation between the Ore Concentration Company and Minerals Separation, in which it was alleged by the former that its Elmore patents of 1898 and 1901 were infringed by the process used by the latter and patented by Sulman, Picard, and Ballot in 1905, has at last been concluded. In the first court the decision went in favor of the Minerals Separation and in the court of appeal the decision was reversed. The case was subsequently re-argued before the House of Lords and their decision was given on November 16. They reverse the decision of the court of appeal and pronounce for the Minerals Separation. Thus it is held that the Sulman-Picard-Ballot process as applied at the works of the Sulphide Corporation at Broken Hill is not an infringement of the old Elmore oil process. The action had nothing to do with the modern Elmore vacuum process which is successfully working at the Zinc Corporation's works at Broken Hill and elsewhere. The Elmore patent of 1898 described the flotation of sulphides by large quantities of heavy oil and that of 1901 stated that the addition of small quantities of acid increased the affinity of oil for sulphides. In the Sulman-Picard-Ballot process, very small quantities of oil are used, together with some acid, and reliance is placed on the buoyancy of air or gas bubbles for the flotation. The Elmore patents were held by the House of Lords to refer to the use of large quantities of oil and, therefore, not to be an anticipation of the patents of 1905. It is impossible here to go into full details. There is a common supposition that the Elmores were the first to discover the affinity of oil and acid for sulphides, which is quite a mistake, as may be seen from a perusal of an article on the 'History of the Flotation Processes' that appeared in the September issue of *The Mining Magazine*. On the other hand, it must be said that the Elmores were the first to evolve a working process, and they deserve the credit for being the practical pioneers of this method of concentration.

GOLDFIELD, NEVADA.

Injunction Against Assayers.—Mohawk Development.—Florence Mill.

The taking of testimony in the hearing of the application of the Consolidated, Florence, and Fraction companies resulted in an injunction against a number of local assayers, restraining them from purchasing ore, concentrate, precipitate, bullion, or other gold-ore products without first notifying the complainant companies and permitting an inspection by their agents, action was delayed by the large volume of work required for the Wells Fargo Express Co.'s agent to prepare a statement of shipments made by that company. The cashier of a local bank produced records showing that bullion shipments had been made through his bank between June 1 and October 2 amounting to \$31,000, and of this amount it is charged that \$26,200 was the product of ore stolen from the complaining companies and reduced to bullion by local assayers who bought the stolen ore from miners. The granting of an injunction of this sort, while unusual, seems to have been amply justified by the facts submitted. Concentrate in particular could hardly in this camp come honestly into the hands of individual miners.

Large bodies of excellent milling ore are being developed at the southern end of the Combination No. 1. and on the Combination No. 2. On the fourth and fifth levels stopes are in places over 20 ft. wide. The ore has been followed

to a point near the boundary line of the Florence, near the workings of the rich Reilly lease. From an adit driven into the Jumbo hill to tap the old workings of the Zinn and other early leases, some high-grade ore is being taken by a small force of miners. Much of the territory formerly under lease on the Mohawk and Jumbo is yielding high-grade ore and a large tonnage of material that had caved in the old stopes has been found to yield good returns from treatment. The workings about the caved Hampton stope are being cleared. Drifts are being driven in good ore toward the old leases at the north of the Mohawk No. 2 claim.

The Florence mine is now making a better production than ever before, and, according to the management, the mill, with its new 200-ton gyratory crusher, may be relied upon for a daily treatment of 160 tons. It is stated by the

Florence Mine and Mill.

president of the company that there is now sufficient ore of good quality blocked and ready to hoist in the workings immediately adjoining the mill to supply the plant for a year without further development. New ground is also constantly being opened with excellent results. At the 350-ft. level a lateral is being driven to a point under the workings of the old Reilly lease. In driving north to this ground the work is almost continuously in paying ore. In October the Florence mill treated 4056 tons of ore with an estimated recovery of \$110,000.

BUTTE, MONTANA.

November Output. — Amalgamated-Clark Litigation. — North Butte-Tuolumne Trouble.

Production of copper by the Butte companies in November aggregated 27,889,140 lb., produced from 409,380 tons of ore, the various concerns contributing to the total as follows:

| Companies. | Ore, Tons. | Copper, Pounds. |
|--------------------------|---------------|--------------------|
| Boston & Montana | 103,800 | 7,785,000 |
| Anaconda | 105,150 | 6,519,300 |
| Butte & Boston | 19,200 | 1,171,200 |
| Washoe | 16,350 | 981,000 |
| Parrot | 11,280 | 654,240 |
| Trenton | 12,000 | 720,000 |
| North Butte | 41,400 | 3,146,400 |
| Butte Coalition | 60,000 | 3,960,000 |
| Original | 23,100 | 1,617,000 |
| Pittsburg & Montana..... | 6,600 | 627,000 |
| Davis Daly | 4,500 | 288,000 |
| Miscellaneous | 6,000 | 420,000 |
| | 409,380 | 27,889,140 |

Pittsburg & Montana production is owned by the East Butte Copper Mining Co., and represents the yield of first-class ore only, little second-class being mined at present. The Coalition production includes that company's share in the output of a number of orebodies mined by associated companies.

Matters are shaping for an important contest in mining litigation between the Amalgamated Copper interests and the W. A. Clark companies. A year ago the Amalgamated served notice on Mr. Clark that he has been mining on ore-

bodies claimed by the Amalgamated, but he treated the notice with slight respect; in fact, he told the messenger to take his notice to a place reputed to have more heat and sulphur than the smelters of Butte. Papers have been prepared, but have not been filed in court, the delay, it being presumed, being due to the copper merger negotiations in New York. Mining lawyers who are not interested in the controversy appear to be of the opinion that the defense of Mr. Clark has little merit. Under the old mining laws, governing the location of the Original and Stewart mines of the Clark company, the limits within which mining could be done were narrow, and it is claimed that long ago Clark passed beyond these and into ground owned by the Amalgamated company, and that, therefore, the Original and Stewart claims practically have been worked out. The shafts of both mines have been sunk deeper and the veins intersected still farther beyond the legal boundaries of the properties, according to the Amalgamated contention. If the Amalgamated should be successful in the courts heavy damages for ore already mined will undoubtedly be assessed. The Amalgamated was involved once before in litigation with Clark over a property owned by him and known as the Colusa-Parrot. The evidence presented at the trial was so clear that in settlement of the judgment Clark turned his mine over to the Amalgamated. To avoid suits over the Stewart and Original questions the Amalgamated frequently offered to buy the properties from Clark, and several times he fixed a price on them. Each time he changed his mind before the deal could be closed. Once he started for New York to close the sale, but between Butte and New York he raised his price \$10,000,000 and the Amalgamated people declined to be 'held up' as they called it. It has been said that Clark has held out on the copper merger because of the pending trouble with the Amalgamated, seeking to force a settlement as the price of his consent to enter the combine.

The outbreak of litigation between the North Butte and the Tuolumne company appears to be rapidly approaching. Both are working on the same vein and orebody, the one claimed by the North Butte as the vein of the Jessie mine. The 1600-ft. level of the Jessie, on account of the higher elevation of the property, is little higher than the 1400-ft. level of the Tuolumne, where the latter company has been developing a large vein north of the Tuolumne shaft. In raising from the end of the 1400 cross-cut the Tuolumne broke into the 1600 workings of the North Butte on the Jessie vein. The latter working is a drift run east from the Speculator cross-cut in the Jessie ground, and is all the way in the Jessie vein, which fact would seem to indicate that the North Butte is working on its own vein and orebody, and that the Tuolumne is on the same vein.

MEXICO.

Railway Extensions.—Power Lines.—Oil War.—Oaxaca Mining.

The National Railways of Mexico have issued for some time past, an advertising magazine under the title of *Mexico Today*. This is to be changed to *The Mexican National Magazine*, and it will be improved and made into a magazine of value, dealing with all matters of interest, historical, scenic, agricultural, mining, and commercial, to be found in the territory covered by the National lines. The contract has been let for the grading of 72 kilometres of the new Vera Cruz al Istmo branch line which will eventually connect Rivas station with San Andrés Tuxtla. This will open up a rich and fertile region. The contractors are McGavock & Borrowe. They have also been doing a considerable amount of work on the Southern Pacific line on the division from Guadalajara northward. The international boundary bridge across the Suchiate river, between Mexico and Guatemala, on the line of the Pan-American railroad, is to be commenced at once. The Mexican Railway Co. has just bought the Córdoba & Huatusco railroad. It is only a small line about 20 kilometres long, extending from Córdoba to San Juan Coscomatepec, and connects at Córdoba with the Mexican and with the Vera Cruz & Pacific roads. It is an important feeder.

A concession has just been granted to Albert A. Tripp

for the right of building a railroad from Miraflores to Ensenada de Santiago, in the State of Colima. The line, when completed, will tap a rich mineral district and will also form a new outlet to the Pacific. The construction of the proposed railroad from Ameca to Chamela, in the State of Jalisco, will soon be commenced. The necessary capital has been obtained by floating in London a company with a capital of over £1,000,000. The line will be standard gauge and 325 kilometres long. It will open important mining districts and will give Jalisco its first seaport on the Pacific, at Chamela. Charles Wittemore has been the moving spirit in financing this enterprise.

It is stated by Emilio Pinzon, the general manager for the Chapala Hydro-Electric & Irrigation Co. that the company will not be able to deliver power in the Hostotipaquillo or Etzatlan districts before April of next year. This is due to the delay in the construction work of their power plant at Puente Grande. Lewis Bradbury, of Los Angeles, who is the principal owner of the famous old Tajo gold mines in the Rosario district of Sinaloa, is down in the Hostotipaquillo district with George A. Tweedy, looking into a number of *antiguas*, with a view to purchase. If the deals are carried through it will mean another large mining and milling enterprise in the district. The mines owned by the Bradburys in Sinaloa are producing about \$50,000 per month and are credited with a total production since the Colonial days of over ₧80,000,000.

The Mexican Pacific Co., of Seattle, Washington, is planning to build an important railroad line in the State of Guerrero which will have a length of over 100 miles, and will connect the port of Zihuatanejo in the northwest with the port of Acapulco. Construction will begin at once. There have been persistent rumors lately regarding the building of a new line from Toluca into the State of Guerrero. The route that has been surveyed will run from Toluca to Coyuca de Catalan on the Balsas river, and then up the river to Tetela del Rio. The project seems to have some relation to the DeKays-Lipton interests, but no definite information can be obtained, as to who is really back of it. The oil war and cut rates continue with all the energy possible, and in some parts of Mexico the price is as low as ₧2.65 per case. The search for new fields and the drilling of wells goes on with unabated zeal. Besides the Mexican Petroleum Co., the Pearson-Aguilar, and the Oil Fields of Mexico Co., there are eight concerns operating and prospecting in the States of Vera Cruz, Tamaulipas, and San Luis Potosi. The Mexican Fuel Co., which is one of the Pierce interests, has found excellent oil in the well recently brought in on the Panuco river, about 30 miles from Tampico. The Mexican Oil Co., an independent concern, will sell the oil from its well to the Waters Pierce Co. The Standard Petroleum Co., a leasing and exploring company, operating in the same district, is closely associated with the Mexican Oil Co. The Southern Pacific interests are sinking a second well between Tampico and Ebanio, to find sufficient oil for locomotives.

A company with a capital of \$2,500,000 is being organized by W. R. Ramsdell to operate the Refugio, Las Animas, and Tres Estrellas mines, and the Amajac reduction works, in the Hostotipaquillo district, in Jalisco. The properties of the Ayutla Mining Co., in Jalisco, which include the Zapatero, San Felipe, and Vesuvio, have been transferred finally to the Carrizo Copper Co., of St. Louis, Missouri. The price was \$60,000, of which the final payment of \$36,000 has been just made.

The Old Mexico Mining Co., operating several gold-silver properties in the Sierra Juarez of Oaxaca, is making plans to increase the size of its cyanide plant. In the same district is the Natividad mine, where the owners are erecting a large cyanide plant which is nearing completion. The plant would have been ready sooner but a quantity of piping was delayed in shipment. This necessitated buying all the local supply of piping in Oaxaca. The total cost of the plant will be about ₧300,000. The company has had to suspend payment of dividends during the erection of the plant as a result of the heavy capital-outlay. There is a large reserve of milling ore on the patio, so that soon after the plant resumes operation dividends can be paid.

CHIHUAHUA, MEXICO.

Railways and Smelters. — Development in San Ignacio Mountains.

A new standard-gauge line is to be built into the Murphy tract, in the State of Durango. This branch railroad will be about 100 kilometres long, and will be built under the supervision of the National Railroads. The capital and guarantees will be supplied from private sources, as the policy of the National is not to invest any further sums during 1910 to 1911, on branch lines or new construction. The backers of this line are Pimentel Brothers, of Mexico City, Joaquin Casasus, Ed. Hartman, of Durango, and several others. They are all heavily interested in the Murphy tract, and in the country that will be opened by the new line. The surveys have been made, and specifications are now being prepared. The daily press has also announced that a line between Gutierrez, on the line of the Mexican Central in Zacatecas, and the city of Durango would be built. As a matter of fact it has been officially stated by representatives of the Towne interests that there is no prospect of the line being built in the near future. The Mexico Northwestern Railroad Co. has let to R. Y. Dudley a contract for grading 40 miles of the line to be built northward from the lumber camp of Madera to Terrazas, in the State of Chihuahua. The Canadian syndicate which owns the concession to build the great dam on the Conchos river has recently bought a large tract of land that will be flooded. The price paid was ₧140,000.

In the Tepehuanes district of Durango, some rich finds have recently been made on the El Conde mine, on the 400-ft. level. The vein varies from one to three feet in width, and the rich ore struck runs from ₧50 to ₧100 per ton, about 25% of the value being in silver and the rest in gold. I. J. Fitzgerald, of Omaha, has just been elected president and general manager of the El Conde company. A concession has just been granted to Luis Terrazas, J. W. Clayton, and Charles Seawell, to build a smelter in the municipality of Temosachic, in the district of Guerrero. The concession runs for ten years with the usual exemption from State taxation. The concessionaires are planning to build a smelter of 100 tons capacity to be placed in the copper-gold-silver district known as Guaynopita, about 40 miles west of Madera. The new railroad will pass within 25 miles of the proposed plant. Quite a number of the Mormon colonists in Chihuahua, own mining claims in this district. It is stated that large mineral tracts have been taken up and are being held, awaiting the building of the railroad. Active work is now going on in the Hauriche canyon near Torreon in view of the probable construction of a railroad line into this district by the Turquoise Copper Co. The smelter of this company will also be enlarged. R. D. Anthony has been appointed superintendent. In the same district are situated the Esperanza, Casino, Rayos del Sol, and Porfirio Diaz properties. J. F. Johnston, acting on behalf of the American Smelters Securities Company, holds a lease on the Jiboa mine at Jimenez, near Parral, and is starting development to prove the property. Some work is also being done on the Los Trenes and Solisas prospects, two shafts will be sunk and the hoisting machinery, which has already been bought, is on its way from Santa Barbara to the mines.

Preparations are under way for more extensive developments on the San Juan and Bonita mines, which are situated in the San Ignacio mountains, about 12 miles south of the Rio Grande. These mines form part of a group consisting of 59 pertenencias, equal to about 147 acres of ground. They are owned by J. E. Townsend, and associates, of El Paso. The vein varies from five to twelve feet in width, and has a calcareous slate roof-wall, and a porphyry hanging wall. The ore is silicious copper, carrying 6 to 12% copper and 4 to 8 oz. of silver per ton. About 1200 ft. of development has been done on the properties. The ore will be shipped to smelters in the States by way of El Paso. The work on the big Palmilla mill for Parral is rushed. The spur track is nearly completed, and work will be started on the concrete foundations for the mill in a few days' time. The structural steel for the buildings is also expected shortly.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Eight cars of 50% copper matte were shipped from the smelter of the Arizona United Mining Co., in the Johnson district, to the Douglas plant to be refined and the company will continue shipping two cars per week.—The new Oliver power plant of the Calumet & Arizona Mining Co. was started recently developing 2000 hp. The current will supply power for the Warren-Bisbee electric road and light for the town of Warren as well as for the Calumet & Arizona properties.—The White Tail Copper Mining Co. has been organized to take over the Doran & Gallagher claims in the Paradise district.—Sinking was resumed at the 135-ft. level of the shaft on the Morrow & Chamberlain group. The bottom of the shaft is now in ore and it is the intention of the owners to ship that taken out in the development to the Copper Queen smelter as was done from the 40-ft. level some time ago.

GILA COUNTY.

The new pumping plant recently installed at the Eureka shaft of the Arizona Commercial Copper Co., near Globe, has lowered the water to the 700-ft. level and work has been started at that point.—The south cross-cut from the Sullivan shaft at the Cordova property, in the Miami district, is in 156 ft. the face being in chalcocite ore of commercial grade. The new shaft is down 30 ft. in the oxidized zone.—One ton of ore from the old Centennial mine sent to the Old Dominion smelter assayed 450 oz. silver per ton with a considerable copper content.

MOHAVE COUNTY.

One of the most important mining transactions ever made in this county was effected a few days ago when all the property of the Arizona-Mexican Mining & Smelting Co., operating the Needles smelter, was transferred to A. P. Anderson of the U. S. Smelting, Mining & Refining Co. The property conveyed includes the smelter and real estate in Needles; the Iron Bar group of mining claims near Siam, and a lime quarry at Vanderbilt, both in San Bernardino county, California; and the following mines in the Wallapai district of Mohave county: Infallible, Star Spangled Banner, Alta, Twins, Blue Lode, Twin Gulch, Champion, Champion No. 2, Twin Gulch No. 2, Arizona No. 1, and the north half of the Winchester. This makes 30 mines and prospects now owned in this county by the U. S. Smelting, Mining & Refining Co.—In the Chloride district, A. L. White and associates of Lima, who recently acquired possession of the Midnight mine, have bonded the adjoining Pinkham mine, and are now examining the contiguous property owned by George Beebe and D. F. Meredith.—At the Bl Metal mine, where Spurr & Cox, Inc., are conducting mill tests for John Hays Hammond, there is reported a find of rich ore assaying as high as \$600 per ton.

PIMA COUNTY.

Several large shipments of supplies are being hauled from Tucson to the Gold Bullion mines in the Baboquivari mountains. The company has been re-opening the mine for the past five months, and has found ore in the shaft and drifts on the 175-ft. level.—The Wayne Development Co. is hauling high-grade ore from its Rochester property in the Cababi mountains to its mill at Weldon. The company is planning to handle custom ores at the plant and will purchase the output tributary to the Weldon mill.

YAVAPAI COUNTY.

(Special Correspondence).—The Arizona Power Co. has its towers up and lines strung into Prescott. A sub-station is being built and electricity will be delivered to the Prescott Electric Co. within 30 days. The Prescott Electric Co. will use at present 600 hp. The Arizona Power Co. is also furnishing about 300 hp. to the Walker district, and 1800 hp. to Jerome from its new generating plant on Fossil creek. The company is equipped to furnish more power and will do so as soon as pending contracts are signed.

Prescott, November 26.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—The shaft at the Argonaut has reached the 3500-ft. level and the management states that indications are good for the payment of steady dividends for a year. The directors recently declared the regular dividend of 15c. and an extra one of 5c.—The Kennedy is sinking the shaft from the 3500-ft. level. In the mill 100 stamps are dropping. About 300 men are employed.—The Bunker Hill is prospecting the 19-ft. vein opened at the 1750-ft. point, 10 ft. of which are reported to assay over \$10 per ton. The company is disbursing regular dividends of 6c. per share per month.—The new mill at the South Eureka is rapidly nearing completion and it is expected that the full milling capacity of 60 stamps will be dropping shortly.

Jackson, November 29.

BUTTE COUNTY.

(Special Correspondence).—The Cape Horn will resume operations within a few days.—New machinery has been installed at the Cohn and work on a large scale is to start.—At the Blue Hawk 25 men are working.—The Blue Lead has resumed operations with a small force. The adit is in 1500 ft. and will be driven 500 ft. farther. Large quantities of cement gravel have been opened.—The city of Oroville has asked for an order restraining the Ophir Gold Dredging Co. from operating on a strip of land within the city limits.—The London Dredger Co., which recently acquired the holdings of Oroville Dredging, Ltd., is reported to be arranging for more extensive work on its property.—The Mammoth Channel Co. is to commence steady production. The new shaft is in an excellent grade of gravel.—The Magalia Ridge Consolidated Mining Co. is working from the main adit.

Oroville, November 29.

CALAVERAS COUNTY.

(Special Correspondence).—The Cross shaft of the Utica is being equipped with new guides and placed in first-class shape. Within a few days it is expected that the mine will resume with a full force.—The directors of the Lightner have decided to sink a new shaft, as the old one is unsafe and costly. It is planned to resume operations immediately.—The Mountain King group, adjoining the Royal Consolidated, has been acquired by T. G. Lockhart, owner of the Florence mine at Goldfield.—The Calaveras Copper Co. is to commence active production at its Union mines. The smelter and concentrator have been repaired and it is expected to produce at the rate of 1,500,000 lb. of copper per month before the end of the year.—The Remer has cut the pay-gravel in the old channel.

San Andreas, November 29.

INYO COUNTY.

Seven carloads of machinery for the 300-ton mill to be erected by the Buckeye Mining Co. at its mine south of Big Pine has been shipped from the East. The company is also to erect a 500-hp. hydro-electric plant on Birch creek and a cyanide annex at the mill. A. A. Casler is superintendent.—A contract has been let to sink the shaft at the Black Canyon claim to the 60-ft. level.

NEVADA COUNTY.

The Sharp claims on Canada hill have been bonded and work will be started in a short time. Drifts will be driven on the Enterprise, Flat, and Greenman veins from which some high-grade ore has been taken in the past.—J. O. Jones, of Nevada City, has secured a bond on the Blue Lead gravel mine at Relief hill, and will commence work in the main bedrock adit in a short time. There are 670 acres along the old Union channel on the property which has been a large producer in the past.—The first 400 ft. of the new shaft at the Mountaineer mine, in the Nevada City district, has been completed, the raise having reached the surface last week. The last 135 ft. of the work was driven in nine days. Work will be started on the 700-ft. level to connect with the 400.

PLUMAS COUNTY.

P. A. Brangler, of Agnew, has obtained a bond on the

Antlered Crest group and the Blue Gravel Consolidated group on Mooreville ridge, four miles west of La Port. The claims cover about six miles of the channel, the opening of which will be in charge of W. T. Frazer.—There are 25 men repairing the ditches and workings at the Plumas-Eureka mine at Johnsville and active mining will be resumed at an early date.—Twenty-five men are working at the Bellevue gravel mine between St. Louis and La Port.

SHASTA COUNTY.

A small amount of oil has been found in the well being drilled by the Bella Vista Oil Co., at Bella Vista, at a depth of 420 ft. The oil was found in a blue shale and drilling will be continued till the sandstone under this is cut.—The Sibyl mine, at French gulch, has been turned over to Fred Bowler and work resumed at the property.—The Bullychoop mine has been closed for the winter.

SIERRA COUNTY.

The channel at the Monte Cristo gravel mine, six miles from Downieville, has been re-opened and gravel assaying between \$5 and \$10 per car found. Fred Phelps is in charge of the work for the company, which owns 1500 ft. along the channel.—The Resasco property, three miles west of Downieville, which is under bond to Lutz & Garbarino, has been shut down for the winter. It is the intention of the operators to install a compressor and drill in the spring.—A drift has been started in the South Fork adit at Forest to open the Maple Grove claims.—The old Centerville mine at Minnesota Flat is being re-opened by Harry Gray and J. M. Fly.

TRINITY COUNTY.

The Globe mine, near Dedrick, has been closed for the winter. The season has been a successful one though somewhat short owing to a break in the ditch.—The Yellow Rose of Texas mine on the border of Trinity and Siskiyou counties has been sold, and it is the intention of the new owners to continue operations throughout the winter.

TUOLUMNE COUNTY.

The adit at the property of the North Fork Consolidated Mines Co. cut the vein when in a little over 100 ft.—A new electric air-compressor is being installed at the Duffield property in the Sonora district and in the future the hoist and pump will be operated by air. The adit cut the vein when in 300 ft. and a shaft will be started on the ore near this point.—The Ralph mine has again been unwatered for examination and it is reported that it will be taken under bond by the examining parties.—Work has been started by William Blackmer who secured the contract to sink a 350-ft. shaft on the west vein at the Jumper mine.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—It is stated that the resumption of work at the Kelly adit will take place shortly after December 1.—The adit at the Rothschilds property at Argentine now in 5000 ft., is to be driven for 3000 more to cut under the rich ore-shoots that were found in the upper workings. Thomas Webb is manager.—The furnaces for the chemical laboratory at the Malm chemical-electro mill, arrived this week and are now being placed in position.—The water has receded over 100 ft. in the last three weeks from the Seven-Thirty shaft workings.

Georgetown, November 27.

(Special Correspondence).—The Ontario-Humming Bird Mining & Milling Co., through its manager, R. Staley, has entered into a contract with Henry Drukker, of Amsterdam, Holland, whereby an option is given upon 206,000 shares of treasury stock at 75c. per share. The first payment is to be made January 15, 1910, while the balance is to be paid in five installments, the final amount to be turned over August 1, 1910.—Work has been resumed at the Hoosac adit on lower Fall river.—The adit of the Syndicate Mining & Milling Co. has been extended for 700 ft., a streak of ore showing in the breast that is 2 or 3 ft. wide, the average value of the product being \$16 per ton in gold. Frank Duffy, of Dumont, is manager.

Idaho Springs, November 26.

GILPIN COUNTY.

(Special Correspondence).—The Topeka mine, in Russell gulch, has been transferred by H. P. Lowe to the Topeka Consolidated Mining Co. Plans are being prepared for the construction of a 100-ton milling plant which will be situated on the mill-site adjoining the Frontenac mill at Black Hawk.—Two carloads of smelting ore sent from the Iron mine assayed 3 oz. gold per ton.—The Ophir-Burroughs mine, on Quartz hill, has been taken under lease by a pool of local business men. A. Waters is manager.—The Rockford mine, in the Russell district, is again being developed, a contract having been awarded to Penaza & Co. to sink the shaft another 100 ft.—Work is to be resumed upon the Homestake property in Lake Gulch district.

Central City, November 26.

LAKE COUNTY.

The spur to the A. Y. and Minnie dumps has been completed and 50 tons per day of zinc ore is being shipped.—The adit of the S. H. Leasing Co., on Sugar Loaf mountain, is in 600 ft., and is opening some good ore.—Work has been resumed in the Baby shaft on Iron hill by the lessees.

OURAY COUNTY.

A dam is being built in Canon creek for the new power plant to be erected at the Thistledown mine just south of

Counties of Colorado.

Ouray.—Recent storms have greatly interfered with the construction of the Mono-Baltic smelter so the plant will not be ready for operations as soon as expected.—A rich shoot of ore one foot wide has been opened in the Wedge property through the Khedive workings and shipping has been started.—Riggs & Cotton have opened a rich body of chalcopryite and gray copper ore on their claims north of Ironton.

SAN MIGUEL COUNTY.

The Gold Pioneer Mining Co., operating leases on the Union, Smuggler, Sheridan, and Mendota dumps, at Telluride, has installed a second washing machine and is separating the ore for 35c. per ton. Henry M. Adkinson is manager.—Regular shipments of concentrate are being sent out from the Alta mill, in Turkey creek basin, with occasional lots of high-grade ore.—A recent washout at the Butterfly mill in the Ophir district took out the spur track to the mill. A light track will be laid to the main line and the concentrate let down in a mine car.

SUMMIT COUNTY.

The dredge in French gulch will be shut down for the winter in a short time. The last clean-up resulted in \$10,500 worth of bullion.—The Sallie Barber mine in the Breckenridge district has been sold for \$65,000. This is considered one of the best zinc mines in the district, and is shipping a car of ore per day from the development work. W. H. Brehmer will remain as superintendent.—The St.

John mine, at Montezuma, has been bonded to Boston capitalists for \$200,000 and a new plant will be erected at the mine.

TELLER COUNTY.

H. P. Relton has secured an 18 months' lease on the Peggy mine on Gold hill on a royalty basis.—The machinery at the Jennie Sample Gold Mining & Milling Co.'s property on Raven hill is being repaired and machine-drills will be installed in the mine by N. H. Merrill, who has a lease on the property.—The Clements Leasing Co. is shipping a car of ore per day from the Gold Sovereign mine that assays from \$15 to \$20 per ton.—The Acacia Gold Mining Co. has declared a dividend of 1c. per share, payable December 20.—The middle block of the Gold Hill claim of the Savage Gold & Copper Mining Co. has been leased to the Success Leasing Co., and the main shaft will be unwatered and re-timbered.—James A. McIlwee, of Cripple Creek, and former superintendent at the Roosevelt Drainage Tunnel, has secured a contract to drive a 12,000-ft. tunnel through Green mountain to bring water from the Laramie river to the Cache la Poudre basin.—The Carol Leasing Co. has been organized to operate a lease on the Monument mine on Battle mountain.—George Dinkins sub-leasing on the lowest level of the El Paso Gold King ground opened a shoot of ore that assays over \$40 per ton.—L. A. Van Tilborg and associates have secured a two years' lease on the Kitty Lane group on Gibbons hill. The lessees have opened a shoot of \$25 ore under a prospecting permit.

IDAHO.

IDAHO COUNTY.

The Buster mine and mill at Elk City has been shut down on account of the heavy cost of shipping the concentrate and disagreement of the officials of the company as to further development. The mill has been running steadily for the past two years on ore from the mine that assayed in the neighborhood of \$50 per ton.—The Majestic Mining Co. is installing a 10-stamp mill and cyanide plant at its property near Dixie. The Majestic company has secured ample water for the mill and has completed a wagon-road to the mill-site.—The dredges in the Elk City district have been closed for the winter on account of the cold weather.

MISSOURI.

LAWRENCE COUNTY.

The Queen City Mining Co. has sold out its leases at McDowell, south of Aurora, to the Metropolitan company, of Springfield, which will resume operations. A new shaft is down 70 ft. in fine ore. This deposit resembles a 'fissure vein' rather than the usual ore run of this region. At Stotts City the mines have begun a period of great development after a long idleness. A central pump station has been established, the cost being assessed pro rata for its maintenance. The water was too strong for one company. The Purdy mines are being revived after many years of idleness. They are shallow silicate properties. A car load was sold last week.

MONTANA.

SILVER BOW COUNTY.

(Special Correspondence).—The Butte Coalition company is now producing nearly 2000 tons of ore per day from the Rarus, Tramway, and Minnie Healy mines, and with its share of ore mined from property owned jointly by the Boston & Montana, Anaconda, and Butte & Boston companies the copper production is probably at the rate of 40,000,000 lb. per year. The company is employing 1250 men at present. While mining is at a rate higher than at any time in the history of the company, development work is still going on extensively. Shaft sinking is going on at both the Rarus and Tramway, the former having reached a depth of 2200 ft., and the latter 2000. Stations are being cut at both points, and when completed sinking will be resumed. It is the intention to sink the Rarus 100 ft. deeper and the Tramway 200 ft. more. New levels will also be started as soon as the stations at the 2200 and 2000 are completed. The large air-shaft on the Rarus, which

has been connected with the workings to the 1600-ft. level, is also being enlarged to a 4-compartment shaft by raising, the waste material being used for filling old stopes. The air-shaft is equipped with a 16-ft. suction fan and provides air for all the Rarus and Minnie Healy workings.

Butte, November 29.

The directors of the North Butte Mining Co. have declared a quarterly dividend of \$1 per share, payable December 23, making a total of \$4 this year which is an advance of \$1 over 1908 and a decrease of \$2 from 1907. It is reported that the cross-cut from the Edith May mine has cut the Jessie vein opening a body of rich ore.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—The Coalition shaft on the Mint has cut promising ore, a good percentage running over \$100 per ton. The shoot is small, but is understood to be increasing in size. The shaft is inclined and is intended to be sunk 1000 ft.—The Marigold lease on Coalition is shipping high-grade and milling ore at the National mill.—The Grutt-Balloon Hill lease on the Queen group has its shaft down 335 ft., but owing to lack of adequate milling facilities development is not hurried. Several strong bodies of milling ore have been opened and compressor and drills installed.—The Victor lease is producing steadily and sending bullion to the mint. The Victor mill is in constant operation.—Sinking on the main shaft of the Kearns has been resumed.—Approximately \$9300 in bullion was sent out from this camp last week.

Rawhide, November 26.

The well which the Nevada-Bay State Oil Co. is drilling near Blair is down over 1800 ft. and has cut a bed of shale in which a small amount of sulphur and asphaltum has been found. The work was delayed for a few days on account of a break in the casing but has been resumed and will be continued till the oil stratum is cut. J. H. Miller is in charge of the work.—It is reported that the Lucky Boy property, at Luckyboy, has been sold to the United States Smelting Co. In the west heading on the 500-ft. level an assay of a sample taken across the vein was 456 oz. silver. On the Silver Moon lease the shaft is down 200 ft. and a cross-cut started for the vein upon which the Hubbard lessees are now working. The winze from the 216-ft. level on the Broken Hills lease is going down steadily and shipments made regularly.—A new hoist is being erected on the Imperial lease on the Atlanta ground at Goldfield by J. H. Houlihan, and the shaft unwatered. When this is finished drifts will be started from the 375-ft. level. On the Matilda and Century leases cross-cuts are being driven for the St. Ives vein.—Work has been stopped at the La Mance lease until a heavier hoist is installed.—Sinking has been resumed on the 675-ft. level of the Grizzly Bear lease on the Grizzly Bear claim of the Consolidated company.

HUMBOLDT COUNTY.

Operations have been resumed at the Monnette property in the Seven Troughs district. The cross-cuts on the 400-ft. level will be extended and the shaft sunk to the 500. M. M. Garoutte is manager.—A whim is to be installed on the Dayton lease on the Buckhorn claims, and the shaft sunk from the 42 to the 100-ft. level. The vein on the surface is 14 ft. wide, and assays from \$7 to \$15 per ton.—The Florence lessees on the property of the Seven Troughs Mining Co. have resumed operations and are getting a shipment ready to haul to the local mill.

LANDER COUNTY.

(Special Correspondence).—The new camp of Bannock is situated about 14 miles in a southwesterly direction from Battle mountain. The ore seems to be found in replacements of basalt and quartzite, heavily stained with iron. At some points considerable granite and limestone is found. The veins of gold-bearing quartz are found chiefly in the older basalt formation.—The Nevada-Omaha Mining & Milling Co. has granted approximately 20 leases on its holdings. The main vein is about 4 ft. wide, with about 6 in. assaying \$100 per ton. From 160 lb. of ore, bullion valued at \$2000 was produced. About 200 sacks of ore are

ready for treatment.—Leases on the Viking have opened a 2-ft. shoot of ore running over \$3 per ton. A short distance north of the camp the Buzzard, Elko-Lander, El Dorado, and other old mines are producing steadily.

Bannock, November 26.

NYE COUNTY.

(Special Correspondence).—The Tonopah Mining Co. is devoting considerable attention to the west section of its holdings. The Red Plume shaft has been placed in active operation to handle the waste, while the ore will be drawn through the Mizpah. The foot-wall drift on the south branch of the Valley View vein has exposed 5 to 6 ft. of milling ore. A new level has been started from near the 700-ft. point of the Red Plume, and cross-cuts will be driven to intersect the new orebodies opened at the 600-ft. point.—The Belmont is practically idle, pending the installation of an ore-washer and repairs to the mill. Aside from limited developments in the lower levels, no work is being done.—The Montana-Tonopah company reports the uncovering of a new vein in the hanging wall of the Triangle vein. It is about 2 ft. wide, and occurs 12 ft. south of the main orebody. The Triangle vein-system has been opened for over 1000 ft.—Lessees are opening a strong body of \$50 ore at the 50-ft. level in the Gold Hill shaft of Jim Butler. Small shipments are being maintained to Hazen.—James Clifford reports that a 5-ft. vein of \$41 ore has been opened by his company at Ellendale.—The Pioneer lease is shipping about \$1000 daily in ore. Recent developments are satisfactory.—The monthly pay-roll of Pioneer ranges from \$24,000 to \$30,000.—The Manhattan Dexter has cancelled the Plamenaz, and Shea & Putman leases. The War Eagle Co. has secured an injunction prohibiting the Dexter from operating on its ground and a triangular fight between Dexter, the War Eagle, and Dexter lessees has been started.

Tonopah, November 27.

STOREY COUNTY.

(Special Correspondence).—The unwatering of the C. & C. shaft to the 2650-ft. level has been authorized by the Comstock Pumping Association, and within a short time the work will commence under the supervision of Leon M. Hall. It is thought that the present pumping plant, with the addition of a centrifugal pump will enable the company to unwater the shaft to the point desired.—The Rosedale group, 16 miles east of this city, has been taken over by Salt Lake capitalists. A 700-ft. adit has cut a vein at a depth of 400 ft. and driving will be started to cut two ore-shoots, which outcrop on the surface. The ore is said to assay \$12 per ton.

Virginia City, November 27.

WHITE PINE COUNTY.

(Special Correspondence).—The Boston-Ely holdings of some 300 acres adjoin the Veteran group on the west. The iron croppings of the Ely district may be traced continuously from Lane City, three miles west of Ely, to about the centre of Boston-Ely ground except on the Ely Central ground near Copper Flat where the rhyolite covers them, extending about seven miles in all. The Emma shaft of Boston-Ely was sunk in limestone for 865 ft. At this point the leached jasperoid was found. This shaft is now down 1050 ft. and still in the jasperoid, and is perfectly dry. It is now felt that as soon as the water level is reached there should be an important enrichment. T. F. Cole has expressed himself as feeling that the conditions here are similar to those at the Irish Mag claim of the Calumet & Arizona property.—Three-quarters of a mile southeast of the Emma shaft is the Alpha shaft of the Giroux Consolidated Mines Co. This shaft was sunk through 1008 ft. of the leached capping before water was found. At the 1000-ft. level a cross-cut was run in a northerly direction, and about 150 ft. from the shaft the first ore, consisting of native copper, was found. The shaft was then sunk 200 ft. deeper, and a good deal of high-grade ore taken out. At the 1200-ft. level, in cross-cutting, an immense body of this same material was found, but the water having increased materially during this work it had to be temporarily abandoned and a new shaft opened. This will be through from

the 1200-ft. level to the surface before the end of January next.—The Veteran orebody of the Cumberland-Ely Copper Co. appears to be an isolated bunch of sulphide ore, assaying about $3\frac{1}{4}\%$ copper, and originally contained some 3,000,000 tons of ore. This occurs on a bench or shelf of limestone in a trough that has protected the sulphide from oxidation and leaching. In the western part of the Veteran mine the oxidized zone becomes much deeper and has not been prospected at all.

Ely, November 27.

Snow and cold weather are proving something of a handicap to the operations of the steam shovels at Copper Flat. However, there has been no falling off in the output and the management is evidently depending upon the Flat for a supply of ore for the entire winter. The Veteran mine is still idle and a good deal of work remains to be done around the Star Pointer shaft before the Ruth mine will be ready for production.—The cold weather is causing the Giroux people a good deal of trouble with their churn-drills, and it is likely that drilling operations will soon be discontinued for the winter. In addition to their churn-drill operations, the Giroux company is also prospecting with a diamond-drill in the deeper levels of the Alpha shaft.—Thomas F. Cole has purchased from C. R. Fuller the Trevarno fraction mining claim, joining the Boston Ely on the south and lying between that property and the Veteran Ely Extension, which latter property also passed into the hands of Mr. Cole not long ago.—Salt Lake papers have announced that the Cole-Ryan interests are the financial backers of Tex Rickard in the construction of the proposed Ely Interurban road which will connect the town with the smelter and mines. The building of this road would give the Giroux company an outlet from its mines to the valley, where it is thought the company's concentrating plant will be built.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The old Ivanhoe property, in the north end of the Black Range district, is again in operation. This mine has been worked intermittently for the last 25 years, usually under lease. It has produced considerable high-grade silver-copper ore, some of which assays high in gold. The El Paso Home Mining Co. is now operating the property and is getting the old workings in shape for production. Martin Fishbeck is manager.—The Elephant Gold Mining Co., owning 15 patented claims in the extreme north end of the district, will begin active operations soon. The purpose is to install heavy machinery to sink the main shaft 500 ft. D. S. Scoville, of Chicago, is president of the company.—The plant recently installed at the old United States Treasury mine, near this place, is in active operation. The shaft is being sunk and level one is being extended to connect for air with White Eagle Shaft No. 1 about 200 ft. north of United States Treasury Shaft No. 1. Sulphide ore has been found which will assay about \$20 per ton.—B. L. Morrison has taken a lease on the Keystone claim in the north end of the camp and has assembled his crusher for shipment. The remainder of his machinery is arranged for, and it is expected that he will start operations in December.

Chloride, November 26.

UTAH.

JUAB COUNTY.

Over 600 ft. of the drainage adit at the Centennial Eureka mine, in the Eureka district, have been completed and the management estimates that the work will be finished by next April. The company recently purchased ground near the portal of the adit and will erect a plant there to supply power for the mine. R. A. Brown is superintendent.—The shaft at the Montana mine is down 200 ft. It is the intention of the company to sink several hundred feet more before cross-cutting.—A new engine has been installed on the 1000-ft. level of the Eagle and Blue Bell mine and sinking resumed.—Operations have been resumed at the Southern Swansea mine.—Power and hoisting machinery is to be installed at the Bradley group in the North Tintic district. M. F. Sammon is in charge of the work.—A.

diamond-drill has been installed on the 1500-ft. level of the Raymond-Illinois mine in the Tintic district. Compressed air will be used for power. J. C. Sullivan is manager.—J. H. Webber, who has an option on the Copper Jack property, is installing a churn-drill to prospect the ground.—The shaft at the Tintic Standard, now down 700 ft., is to be sunk through the quartzite and cross-cutting resumed.—Shipping has been resumed at the Scranton mine, three carloads having been sent out last week.—The Zuma mine has been closed down temporarily.

SUMMIT COUNTY.

Hoisting has been stopped temporarily at the Silver King Consolidated property while a new head-frame and ore-bin is installed. A shipment of 60 tons of lead-silver was forwarded to the smelter.—The Uintah Treasure Hill Mining Co. has filed suit against the Silver King Coalition Co. asking for an accounting and a division of the claims which the companies own jointly.—The Daly-Judge Mining Co. is installing a large new compressor at its Park City mine.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—R. J. Howard, of Spokane, has become general manager for the New Republic company. Mr. Howard is one of the largest shareholders in the company.—The Tom Thumb mine has been drained to the 300-ft. level.—The Ben Hur Leasing Co. is extracting and shipping about 200 tons of ore per week.—The Southern Republic company has drained the Princess Maud mine and is now installing at the shaft a 32-hp. gasoline engine. As soon as it is ready to operate, the compressor will be started and work will be resumed on the 600-ft. level.—The Bodie claim, supposed to be traversed by the southerly extension of the San Poi vein, has been sold to J. R. Johnson and associates.—A streak of rich ore exposed in the upper adit of the Flag Hill mine is being stripped and will be broken down for shipment to the smelter.—Covada, a rich camp in the southeastern part of the county, has become unusually active. Operations are to be renewed in the Keystone mine and new track is being laid in the adit for that purpose. An adit of the Southern Cross mine, now in 700 ft., will be extended. At the Imperial mine the adit will be driven ahead during the winter. A 10-in. streak of rich galena ore has been intersected by the adit in the Plymouth Rock mine. A wide vein of rich antimonial ore, mainly stibnite, has been found in the Robert E. Lee mine. Work has been resumed at the Sunflower group. At the New York mine operations are to be resumed soon.

Republic, November 29.

OKANOGAN COUNTY.

(Special Correspondence).—The Arlington mine at Ruby, on Salmon river, was first opened by a 300-ft. shaft, and later by an 1100-ft. cross-cut to the vein, opening it at 450-ft. depth. About 100 ft. of driving has been done on the vein at this level, showing it to be 4 to 12 ft. wide and between granite walls. The ore consists of quartz with gray copper, silver, and chalcopryite. The ore obtained from the last 25 ft. of driving averaged 138 oz. silver and 3.4% copper. H. S. and J. E. Stoolfire, of Spokane, are managing the property. A hydro-electric plant and concentrating mill may be installed next year.

Conconully, November 26.

(Special Correspondence).—It is reported that ore assaying 60% tin has been found on Chelan Butte; that it had been mined and on the dump for two years, unknown to the owners, and the presence of tin was only recently discovered by an assayer.—A new vein has been found in the lower adit of the Bodie mine, owned by the Duluth-Toroda Mining Co., the ore averaging \$15.38 per ton. From a recent clean-up in the mill two gold bars were shipped, valued at about \$750.—A carload of concentrate was shipped from the Nighthawk mine.—James P. Blaine, the superintendent of the Apex mine, near Chesaw, has prepared a contract for the purchase of a 10-hp. air-compressor, two Sullivan drills, a 35-hp. engine, a steel cage, cable, and 800 ft. of steel rails.

Chesaw, November 27.

STEVENS COUNTY.

(Special Correspondence).—The lawsuit against the Valley Dew Mining Co., in the Superior Court of Washington, has been settled out of court. Work has been resumed in the mine, and a contract has been let to extend the adit 350 ft.—A contract has been let for driving a cross-cut through the vein in the North Star mine. There are two other cross-cuts, one 70 and the other 145 ft. long.—It is reported that ore, assaying as high as \$2000 per ton in gold, has been uncovered on the lowest level of the First Thought mine.—The Columbia River Gold Mining & Development Co. has started an adit at the base of Gold hill, to tap the Cougar and Right Side veins. Several carloads of ore have been shipped from the Right Side vein, which paid the expense of development.

Orient, November 27.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The lessees of the Velvet-Portland mine shipped a trial lot of ore to the Trail smelter during the past week and will soon be shipping regularly.—The shaft at the Le Roi No. 2 is now down nearly to the 1300-ft. level. The mill is running 24 hours per day on second-class ore.—The weekly shipments of the Consolidated Mining & Smelting Co. amounted to 4219 tons. The Consolidated smelter at Trail also received 4400 from the Snowshoe in addition to the shipments from the Nelson district.—The billion dollar copper combine has aroused no little interest in this district, especially as it is rumored that the Granby company, now counted an important factor in the American copper situation, will very likely be absorbed. If this ultimately proves to be the case there is no doubt the Morgan trust or merger intends to control the copper output of the Boundary, as New York copper men now control the destinies of the B. C. Copper and New Dominion Copper companies.

ONTARIO.

At the Temiskaming a winze is being sunk from the 340-ft. level 300 ft. from the main shaft. This is the lowest working in the South Coleman district, and is in good ore.

McKinley-Darragh Mine, Cobalt.

There are 14 drills running in the mine and the success attained by the Temiskaming company has encouraged the others to sink, the result being that most of the larger properties of the district are deepening their shafts.—The Newman claim, in the South Lorrain district, has been purchased by local capitalists and will be known as the Bellellen Silver Mines.—The Hudson Bay Mining Co. paid a dividend of \$3 per share on November 23. This is at the rate of 300%.—Charles Gifford, of Toronto, purchased the Porcupine claims in the Porcupine district from Herbert Fade for \$20,000.—Lot A.55 of the Gilles Limit was sold by the Government for \$35,000, the largest price paid for a lot during the sale. There were 55 lots sold bringing \$362,786.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

FRANK H. PROBERT is in Arizona.

C. H. WILDMAN is at Norwalk, Ohio.

NORVAL J. WELSH is in Chihuahua, Mexico.

W. C. MENDENHALL has gone to Los Angeles.

F. B. WEEKS was in San Francisco this week.

H. W. TURNER has returned from Downieville.

A. E. DRUCKER is touring Scotland and England.

A. CHESTER BEATTY was in San Francisco last week.

P. GEO. GOW has returned to California from Europe.

ROBERT ALLEN, lately in Mexico, has gone to the Rand.

E. T. MCCARTHY has returned to London from Siberia.

F. K. BORROW has returned to London from Manchuria.

HENRY HAY returned to Johannesburg early in October.

WALTER HARVEY WEED will be in New York December 20.

J. M. BOUTWELL has been at Washington, District of Columbia.

H. KILBURN SCOTT has left for Spain on professional business.

EDGAR COLLINS is enjoying a vacation at Santa Barbara, California.

F. L. LOWELL, of Alleghany, California, has been in San Francisco.

FRANK J. PARIZEK is with the Inspiration Copper Co. at Globe, Arizona.

F. EWING, recently with the Inspiration Copper Co., Globe, Arizona, is at Butte.

WALDEMAR LINDGREN is lecturing at the Massachusetts Institute of Technology.

R. S. RAINSFORD has been recuperating in Scotland and has now returned to California.

GEORGE J. YOUNG, of the Mackay School of Mines, has gone to Europe on a vacation trip.

COURTENAY DE KALB addressed the mining students at Stanford University, November 30.

A. W. TAYLOR and W. W. TAYLOR, of Seoul, Korea, have been visiting California dredging fields.

W. L. BELL, mining engineer, has opened an office in the Jamieson building, Spokane, Washington.

R. B. LAMB, of the C. L. Constant Co., is making a professional visit to the silver district of Canada.

W. A. CLARK sailed from London on the *Mauretania*, November 20, for a trip of inspection of his various holdings in the Western States.

N. E. LINSLEY, mining engineer, of Spokane, visited the Granby mines and smelters at Phoenix and Grand Forks, British Columbia, last week.

H. C. WILMOT, who has been in northern California and southern Oregon for the past month, has gone to New York and may be addressed at the Engineers' Club.

S. W. OSGOOD has become associated with F. J. Peck & Co., chemists, assayers, and metallurgists, of Cleveland, and will represent them in Chicago with offices at 164 Dearborn street.

C. E. STEVENS, formerly of the Bagdad Chase Gold Mining Co., and superintendent of the Petit mine, Atlanta, Idaho, is now superintending a new mine on Skelton creek, near Soldier, Idaho.

MASON T. ADAMS has resigned as general manager for the Britannia Mining & Smelting Co., in British Columbia, and opened an office as mining engineer in the McPhee building, Denver, Colorado.

HERBERT M. WILSON, J. C. ROBERTS, and A. C. RAMSEY, of the Geological Survey, are giving lectures to the bituminous coal miners of Tennessee on the work of the Pittsburg experiment station. A sub-rescue station has been established at Knoxville, Tennessee, in charge of Mr. Ramsey.

Dividends.

The directors of the Copper Range Consolidated Co. have declared the regular quarterly dividend of \$1 per share. Previous dividend payments have been as follows:

| Year. | Per share. |
|-------------|------------|
| 1909 | \$4 |
| 1908 | 4 |
| 1907 | 6 |
| 1906 | 6 |
| 1905 | 4 |
| Total | \$24 |

Saturday, December 4, 1909, the Bunker Hill & Sullivan M. & C. Co. will pay Dividend 147 of \$45,000. This makes the amount of dividends paid since January 1, 1909, \$615,000, and the total to date \$11,286,000.

The Round Mountain Mining Co. will pay on December 20, 1909, to the stockholders of record on December 15 a dividend of 4c. per share.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF MINING LAND.

A deed purporting to convey "all minerals underlying the land described," was held not to be a conveyance of the natural gas thereunder, where, taken in connection with all the evidence, it appeared that the parties did not intend a conveyance of the gas.

McKinney v. Central Kentucky Natural Gas Co., (Ky.) 120 S. W. 314, June '09.

LOCATION OF MINE—FAILURE TO PERFORM ASSESSMENT WORK—ADVERSE POSSESSION.

A person who enters upon the mining claim of another during the year within which the owner of the claim is required to perform the assessment work, and who holds possession thereto, adversely to such original holder, will not be heard to object that such original holder had not performed the annual work required by law.

Madison v. Octave Oil Co., (Cal.) 99 Pac. 176, Dec. '08.

MINERAL LAND—WHAT CONSTITUTES.

It is not sufficient to render lands valuable for mineral, under the United States Statutes, reserving from sale lands valuable for minerals, that there is some trace of mineral on such land, but there must be minerals in such quantities as to justify the expenditure and effort to recover them. However, it is not necessary that minerals of sufficient amount and value to allow immediate profitable working be shown to exist in the land, but it is enough if the vein or deposit has a present or prospective commercial value.

Madison v. Octave Oil Co., (Cal.) 99 Pac. 176, Dec. '08.

RIGHTS IN SUBTERRANEAN MINERAL WATERS.

Subterranean mineral waters are regarded in law as minerals in respect to their use and enjoyment without reference to the quantity of salts and gas which may be in solution. An adjoining proprietor was entitled to equitable relief independent of any statute to prevent another proprietor from increasing the flow of percolating mineral waters and gas by means of pumps, so that he obtained a greatly increased proportion of a common supply at the expense of such adjoining proprietor for the purpose of supplying a public market with gas, and turning the mineral water to waste.

Hathorn v. National Carbonic Gas Co., (N. Y.) 87 Northeast. 504, Feb. '09.

MINING CORPORATION—APPOINTMENT OF RECEIVER.

In an application for the appointment of a receiver for a mining company, the evidence showed that at the time of the trial the mining property of a mining corporation, including the mines, the development work, and the machinery, had cost the company more than \$40,000; that they were estimated to be worth at least \$50,000, and that the mines were being operated and were producing between six and seven tons of ore per day at a net profit of \$4 per ton, and that the total indebtedness of the corporation was about \$4000. It also appeared that the creditors of the corporation were not complaining. This did not show the insolvency of the corporation sufficiently to justify the appointment of a receiver. And the fact that the directors had ordered the payment of a salary of \$100 per month to the president as manager of the mines and that the president had applied certain sums in payment of his expenses for attending the meetings of the corporation, and the fact that certain stockholders upon inquiry at the main office, were not furnished with all the information they desired, and did not obtain copies of the by-laws when demanded, were not such acts as would constitute mismanagement sufficient to justify the appointment of a receiver of a solvent corporation.

Secord v. Wheeler Gold Min. Co., (Wash.) 102 Pac. 654, June '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

ORE DRESSING. By Robert H. Richards. Vol. III and IV. Pp. 1199—2052, ill. Index separate. McGraw-Hill Book Co., New York, 1909. Price, \$5 per volume.

A TEXT BOOK OF ORE DRESSING. By Robert H. Richards, assisted by Earl S. Bardwell and Edwin G. Goodwin. Pp. 702, ill., index. McGraw-Hill Book Co., New York, 1909. Price, \$5.

The great treatise on ore dressing by America's dean of ore dressers is now complete, and is rounded out by a comfortable summary suitable for classroom use as well as for a *vade mecum*. Robert H. Richards has done for our day what Rittinger did for the mining world of more than half a century ago. Like Rittinger he has produced a work of permanent value, a technologic classic. Though the art will continue to advance in perfection, the work of these two masters is fundamental, and will live. Richards has contributed more original knowledge than his predecessor. His experimental investigations have covered the field of concentration with the aid of water so fully that little remains to be done except in the study of some of the more obscure phases of the settling of solids from suspension, and it is reasonable to suppose that Mr. Richards will presently throw light upon these problems in a supplementary volume. Perhaps the most notable service rendered by the author has been the exhaustive study of the principles of jigging and of hydraulic classification. He gives his final dictum in favor of sizing as a preliminary to jigging, while admitting the practical efficiency of the English system of treating material roughly sized between wide limits. His own contribution to practical jigging has been the design and successful development of a jig which dispenses with reciprocation, the water being forced constantly upward by rapidly alternating impulses. The result has been to increase the cleanness of product obtained, and to enormously augment the capacity per unit of area in the jig. He has also developed a hydraulic classifier in which a remarkably successful attempt has been made to overcome the difficulty of interfering currents by imparting a rotary motion to the separating water-column.

In the discussion of ore-crushing in Volume III, occur important summaries and analyses of the latest studies of the subject. The work of Philip Argall upon roll-crushing is thoroughly reviewed, giving results reached concerning the relation of speed to size of material fed, and of the mechanical details which have proved most important. Anyone familiar with roll-crushing will appreciate the difficulties which have arisen in the use of these machines from imperfect design and construction, and the discussion given here will accordingly be particularly welcome. The work of Courtenay De Kalb on the laws of crushing is also stated in large detail, and the principal facts determined as to how ore-particles are crushed are set forth with the aid of diagrams and curves. The theory of tube-mill action is elaborately explained, due credit being given to the researches by H. A. White; and the mathematical analysis of the power required for crushing, as worked out by E. A. Hersam, is also reproduced. The chapters on stamp-mills are replete with data; and there is a review of all the recognized systems of crushing. Other chapters deal with sizing screens, and the principles of screening, in which the later improvements are dealt with in detail. A chapter on miscellaneous processes of separation gives a discussion of magnetic and electro-static concentration, with many illustrations, and all the flotation processes which are gaining in favor steadily. A chapter of great practical merit is a summary of principles and outlines of mills, followed by another on general ideas on milling, in which is treated the question of power-tests, water consumption, percentage of extraction, cost of erecting mills, working costs, testing for methods, and appliances suitable to given ores, and regular mill-testing. The work is absolutely indispensable to any student of milling operations. A large part of Volume IV is given up to details of milling plants, constituting a most useful summary.

The text book is wholly admirable. Although it contains a reprint of much that appears in the larger treatise, it also comprises new matter, and the gathering of the whole subject into this form makes a work of great value for ready reference. Mr. Richards has performed a service of enormous benefit to the mining world in the preparation of these splendid volumes. It has been a labor of love. By no possibility can the cost ever be returned to the author, and he deserves the honor and gratitude of his professional brethren throughout the world for his masterly and self-sacrificing labors.

A STUDY OF THE OPEN HEARTH. By Harbison-Walker Refractories Co., Pittsburg, Pa., 1909. Published by the Harbison-Walker Refractories Co. for private circulation.

A better example of advertizing in an effective manner would be hard to find than this little book. It is produced in the form of an *édition de luxe*, handsomely printed on elegant paper, and tastefully bound in limp leather. There is no mention from cover to cover of any article which the company has to sell, and its own products are not even mentioned in the text of the treatise; but no one can read this scholarly little book on furnace construction and maintenance, and on the metallurgical operations in connection with the basic and acid open-hearth steel processes, without feeling that the company responsible for its authorship and publication must be competent to render effective aid to those in need of materials for furnace work. The open-hearth process is today producing more steel in the United States than the bessemer process, the figures for 1908 being respectively 7,780,872 and 6,116,755 tons. The statement is also made that it is wholly improbable that any new bessemer plants will ever be erected. The discussion of furnace construction, materials for walls, roof, and bottom, and the method of building and smelting in bottoms, is wholly admirable. It should be of great service, by way of suggestion, to anyone having responsibility for furnace work in connection with the smelting of other metals. The difficulties experienced with different refractory furnace linings are well set forth. No mention is made of the methods employed for sintering chromite in Europe, nor of recent promising attempts in this country. The virtues of magnesite are explained, and analyses of such material given.

REVISTA ECONOMICA. Boletín Mensual. Tegucigalpa, Honduras, Central America.

It is not often that one sees so well edited a periodical in Latin America as this new journal, which has undertaken to forward the welfare of Honduras. It is full of interesting information on practical affairs, agriculture, mines, finance, and communications. Typographically the journal is as remarkably good as is its editing. The work is under the direction of Baron de Franzenstein, who is president of the Economic Society of Tegucigalpa.

MODERN PRACTICE IN MINING. VOL. II. THE SINKING OF SHAFTS. By R. A. S. Redmayne. 8vo., Pp. 275, ill., index. Longmans, Green & Co. Price, \$2.25.

This is a thoroughly practical book describing in detail methods used in sinking English colliery shafts. It is well printed and bound, but is marred by being written in a language so full of localisms as to be in parts almost unintelligible except to the engineer who already knows English methods so well as not to need the book.

EIGHTEENTH ANNUAL REPORT, BUREAU OF MINES (ONTARIO). Vol. XVIII, Pt. 1, 8vo., ill., index. Toronto, 1909.

As is usual the report of this Bureau is full of interesting and valuable papers. T. W. Gibson contributes a statistical review of the mineral industry for 1908, showing a total production of \$25,019,373. This is followed by a general account of the mines of Ontario by E. T. Corkill, and a series of papers descriptive mainly of the various iron ranges.

MANZANO GROUP OF THE RIO GRANDE VALLEY, NEW MEXICO. By W. T. Lee and G. H. Girty. Bull. 389. Pp. 120, pl. 12. Washington, 1909.

COMPANY REPORTS.

LAKE VIEW CONSOLS, LTD.

The gold mine at Kalgoorlie, Western Australia, belonging to Lake View Consols, Ltd., continues to make a fair profit, though the ore is of much lower grade than in the earlier days. During the year ended June 30, the 70 stamps treated 98,962 tons without amalgamation. The crushed product yielded 9606 tons of concentrate, which was roasted, slimed, and cyanided, yielding 15,854 oz. of gold, while the remaining 89,356 tons were ground to slime and cyanided, yielding 10,839 oz. gold. In addition 111,464 tons of old slime were treated, yielding 6760 oz. gold, and 232 oz. were recovered from cyanide slags. The total production was, therefore, 33,865 oz. realizing £145,464. The working cost of treating the current production, including development, was £1 1s. 3d. per ton, and the recovery was £1 3s. 3d. The cost of treating the old slime was 2s. 6½d. and the recovery 5s. 2½d. The total working expenditure was £119,718, leaving a profit of £25,746. The amount treated in the mill was less than in the previous year, when 129,110 tons were crushed. Development during the year has brought to light 91,475 tons additional ore, but no new orebody has been discovered. The total ore reserves on June 30 were 172,050 tons. The company, in addition to operating the mine, owns 60,675 shares in Broken Hill South Blocks and has a large holding in the Burma Mines, Ltd., also shares in several smaller companies. The most recent speculation is in connection with South American oil. There is a reserve fund in sound investments amounting to £47,000. The interest in Golden Links terminated in April and the ore from this mine is not now being treated at the mills. The total profit made by the company during the year under review was £33,075, out of which £17,479 has been paid as dividend, being at the rate of 5% on the paid up capital. During the year the company has had a dispute in connection with the price of its water supply. In 1906 the mine was certified as low grade, and therefore entitled to receive water at 3s. 6d. per 1000 gal., but since then attempts have been made by the public authority to rescind this arrangement and charge 5s., the full rate.

Murex Magnetic Process.

Written for the MINING AND SCIENTIFIC PRESS

By ERNEST LEVY.

The Murex magnetic process is for the separating and concentrating of the valuable content of an ore by taking advantage of the affinity of certain oils for the metallic sulphides. The oil is charged with finely divided magnetite or some other magnetic mineral or metal, making a homogeneous mixture. This is added in suitable proportions to the crude ore and agitated in a mixer, the ore having been previously crushed to a size found necessary for liberating the metallics from the gangue, until the sulphides are coated with the magnetic paint. With some ores it is found advisable to add a small percentage of acid before agitating. The whole mixture is then passed at a suitable speed between the poles of an electro-magnet arranged with a moving belt which carries off the magnetic particles; the latter are thereby withdrawn and separated from the remainder and are collected, while the gangue is run to waste. The power necessary for the magnet and agitators is extremely low. The magnetite or magnetic mineral can be recovered from the concentrate after removal of the oil, and can be utilized again. The quantity of oil used is small, varying in amount with the ore being treated. Various oils are applicable to the process, including the residuum oils, producer-gas oil, gas residuum, creosote, and so forth. It will thereby be understood that the necessary adjuncts to the process show a large range, and in any district the oils and magnetic minerals most easily and cheaply procurable can be used.

A second feature of the invention consists in mixing a certain solution with the concentrate, which has the property of breaking the adhesion between the component minerals, and affording a more perfect separation of those minerals in the case of further concentration. As an example,

if a zinc-lead ore had received its first concentration by the Murex magnetic process, whereby a combined lead-zinc concentrate was produced, this could be mixed with the solution and passed over some form of concentrating table. By this means a much cleaner lead concentrate and a much cleaner zinc concentrate would be produced than would have been possible had the solution not been employed. Tests have been made on various ores and good results achieved. It is proposed to erect a testing works in British Columbia, probably at Rossland, where ores will be treated, and all information supplied.

Silver Consumption and Market.

Largely because of India's demand, silver prices have improved somewhat. Silver for 1908 exported from London to India was \$45,073,535, compared with \$51,865,696 for 1907 and \$73,898,224 for 1906. There has been a progressive decrease in India's demand, due largely to changes in the monetary system, which put the metal at a disadvantage and also to the less favorable agricultural condition. Of a world's consumption of 92,568,300 fine ounces of silver, British India took 34,848,500. The various countries as consumers of both silver and gold in the arts and industries compare:

| | Gold. | Silver, fine ounces. |
|---------------------------|---------------|-------------------------|
| United States | \$33,549,500 | 22,137,200 |
| Great Britain | 14,500,000 | 7,500,000 |
| France | 15,850,700 | 8,252,900 |
| Germany | 11,000,000 | 6,500,000 |
| Switzerland | 7,310,600 | 2,218,300 |
| Italy | 3,000,000 | 2,000,000 |
| Russia | 5,700,500 | 3,915,300 |
| Austria-Hungary | 3,358,800 | 1,923,700 |
| Netherlands and Belgium.. | 1,500,000 | 1,000,000 |
| Sweden | 465,200 | 257,200 |
| Colombia | 15,000 | 15,200 |
| Other countries | 3,000,000 | 2,000,000 |
| Total | 99,250,300 | 57,719,800 |
| India (British) | 35,796,200 | 34,848,500 |
| Grand total | \$135,046,500 | 92,568,300 |

Samuel Montague & Co.'s London silver circular says: "China continues the mainstay of the silver market. There is room for suspicion that a heavy fall of exchange with China would be fraught with danger to the smaller importing firms, and that a judicious support by the exchange banks is being exercised to prevent inconvenience to these firms until import business resumes activity. China is endeavoring to become more independent of the West, desiring to profit by its own labor and secure a fair share of the world's increasing wealth. The Prince Regent has instructed the Grand Council to issue a proclamation exhorting that future railways should be financed and controlled by the natives of China. There is also a tendency to import raw material into China in preference to the manufactured article—notably cotton."

Standard Oil Profits.

The following table shows the net profits, dividends, and surplus after dividends of the Standard Oil Co. from 1882 to 1909, inclusive, earnings for the years 1907, 1908, and 1909 being estimated:

| Year. | Profits. | Dividends. | Surplus after dividends. |
|---------------------|-----------------|---------------|-----------------------------|
| 1909 | \$80,000,000 | \$39,335,320 | \$40,664,680 |
| 1908 | 80,000,000 | 39,335,320 | 40,664,680 |
| 1907 | 85,000,000 | 39,335,320 | 45,664,680 |
| 1906 | 83,122,251 | 39,335,320 | 43,786,931 |
| 1905 | 57,459,346 | 39,335,320 | 18,124,026 |
| 1904 | 61,670,110 | 35,188,266 | 26,481,844 |
| 1903 | 81,336,994 | 42,877,478 | 38,459,516 |
| 1902 | 64,613,363 | 43,851,956 | 20,761,407 |
| Total | \$593,202,064 | \$318,594,300 | \$274,607,764 |
| 1882 to 1902, inc.. | 456,240,000 | 351,883,000 | 104,407,000 |
| Total | \$1,049,442,064 | \$670,427,300 | \$379,014,764 |

Arizona Copper Co.

A correspondent of the *Finnacial Times* brings out the fact that notwithstanding the strain of large capital expenditures the Arizona Copper Co. has run a close dividend race in recent years with Rio Tinto.

| | Rio Tinto, Arizona, | |
|------------|---------------------|-----|
| | % | % |
| 1904 | 70 | 60 |
| 1905 | 80 | 75 |
| 1906 | 110 | 105 |
| 1907 | 87½ | 75 |
| 1908 | 55 | 50 |

Undoubtedly the great strength of the Arizona company for the future lies in its small ordinary share capital, as compared with the output of copper. The following comparison is interesting:

| | Ordinary share capital. | Output tons (2000 lb.). | Capital per ton copper produced. |
|-----------------|-------------------------------|-------------------------------|--|
| Arizona | £379,974 | 17,000 | £22½ |
| Rio Tinto | 1,875,000 | 39,000 | 48 |
| Anaconda | 6,000,000 | 50,000 | 120 |
| Mt. Lyell | 1,200,000 | 8,000 | 150 |

Commercial Paragraphs.

The U. S. FLEXIBLE METALLIC TUBING Co. has established a branch office at 425 First National Bank Bdg., Houston, Texas.

The HOOKER ELECTROCHEMICAL Co. has purchased the plant and business of The Development & Funding Co. The same interests will control and manage the business as heretofore.

THE DENVER ENGINEERING WORKS Co. announces the appointment of Walter H. Trask, Jr., as district sales manager at Salt Lake City to succeed Carroll Helmick, resigned. Mr. Trask is a graduate of Massachusetts Institute of Technology and has been a salesman at the company's main office in Denver for the past two years.

THE PARTRIDGE HOT BLAST SMELTER Co., El Paso, Texas, has sold a 10-ton smelter to the Bonney Mining Co., at Lordsburg, New Mexico, and a 15-ton plant to J. B. Heymes, at San Lorenzo, Sinaloa, Mexico. A test run on 10 cars of ore from the Helvetia company of Pima county, Arizona, is being made at the 25-ton plant of the smelter company at El Paso. If satisfactory results are obtained a 300-ton plant will probably be built.

Catalogues Received.

UNION STEAM PUMP Co., Battle Creek, Michigan. Catalogue B. 'Air Compressors'. 72 pages. Illustrated. 6 by 9 inches.

THE JEFFREY MFG. Co., Columbus, Ohio. Catalogue No. 81. 'General Chain Catalogue'. 368 pages. Illustrated. 6 by 9 inches.

WESTINGHOUSE ELECTRIC & MFG. Co., Pittsburg, Pennsylvania. Circular 1181. 'Portable Direct Current Ammeters and Voltmeters'. 8 pages. Illustrated. 7 by 10 inches.

THE CYCLONE DRILL Co., Oroville, Ohio. 'Diamondite Core Drills'. This little booklet describes this device and discusses the advantages of prospecting with drills compared with shaft sinking. 8 pages. Illustrated. 8 by 11 inches.

BISMUTH has been produced in a small way in the United States. Until the last two years these ores have been shipped abroad for reduction, but plants at St. Louis, Missouri, and Grasel, Indiana, are now recovering bismuth from lead ores. Bismuth is contained also in ores of other metals than lead, but most of it that is now mined passes unrecovered out of the smelter flues. It is estimated that 880 lb. of bismuth are thrown off every day in the smoke and gases of the Washoe smelter. Bismuth is used in low-fusing alloys such as are employed in the automatic sprinklers that are common in large warehouses, and in solders, some of which, it is said, can be used under hot water.

EDITORIAL.

SAVING at the Washoe smelter is reported to amount to 76 to 80 per cent of the value of the crude concentrating ore. The extraction at Great Falls is less and at the Clark smelter is said to be 70 per cent.

ELECTROLYTIC copper sold as high as 13.57 cents in November. The average price for the month was 13.125 cents per pound. Sales of over 300 million pounds were made, some orders being booked for delivery as far ahead as March 1. Meanwhile the surplus was increased by 14,304,640 pounds.

TRADE excursions are becoming common. The Japanese have just been visiting us, and now business men of the West Coast are to pay a call to Mexico and Central America. In January and February the steamer *Erna* of the Jebsen line is to make the round trip, going as far south as Corinto. Journeys are to be made inland to the principal cities of Mexico, Guatemala, Salvador, and Nicaragua. Such an excursion should have an important influence in promoting good relations and stimulating trade.

AUSTRALIA is well served by mining journals and has a number of excellent publications. The *Australian Mining and Engineering Review* has just celebrated its second birthday with an excellent review number. In the seventy years since gold was discovered Australasia has produced ores valued at £714,760,000. Of this, gold has amounted to over 71 per cent. In 1908 the combined total mineral output of the Commonwealth and New Zealand amounted to £28,409,576. It is difficult to determine what part of this great development is due to the activities of the mining journals, but the portion must be large. With the excellent prospects for an increasingly important mineral industry, our contemporaries in the South Pacific should find a large field for usefulness. The *Review* seems to be finding an important and deserved position among them.

ANNOUNCEMENT of serious inroads upon the world's available supply of copper ore, that is attributed to Mr. J. Parke Channing by our New York correspondent, will awaken anxiety in some quarters and will quicken speculation in others. Mr. Channing is possessed of superior information on the subject; but in a world still incompletely explored, is it not a bit unsafe to cry exhaustion of resources? The British alarm over the coal-supply on the 'tight little island' was calmed by deeper drilling. Brazil looms up with an iron supply which will hold down the prices of iron-ore lands in many countries; we have yet to hear from enormous areas of South America and Africa, where only the conspicuous cop-

per deposits are known. Mr. Channing would not excite undue cupidity for merger stock, when made available, but, whether right or wrong, his statement, if unmodified, will develop some interesting features in the market.

Strike at the Homestake Mines.

After a period of pleasing calm, warfare between the Western Federation of Miners and mining capital has broken out anew. The strike which has been called at the Homestake mines, in South Dakota, is a signal by which we might feel assured of returning financial vigor, if other evidences were wanting. Strikes are usually a sign of prosperity, not of hardship. During the months after the financial bubble burst in 1907 the Western Federation subsided into inconspicuous good behavior. Its very existence would have been generally forgotten save for a struggle by the faction of law and order to gain control of the organization at the last election of officers. The Western Federation in itself is not necessarily bad. It is capable of becoming an engine for the doing of useful work. It all depends upon the spirit of those in control. The dominant influence of the moment represents that active minority which contrives to rule in so many organizations of men; the kind of influence that produces political corruption, and which stands inevitably and everywhere for illicit gain. Under broad and intelligent guidance the Western Federation of Miners could prove at once the friend of the miner and of the mine operator. The miner wants fair wages and fair treatment, and it is his right to obtain them, by organization or by other lawful means. The mine operator wants efficiency and co-operation toward an economic result. If the union will recognize efficiency as in the last analysis the reason for protection, and will acknowledge responsibility for the capable discharge of duty as a condition for sustaining its members in their differences with employers, the mine operators could find no better labor bureau from which to draw their supply of workers than from the organization itself. It is because the Western Federation declines to recognize efficiency, and instead of offering the kernel of skilled labor would compel acceptance of a mere empty shell of unionism, that it is not accepted and dealt with as an economic agent in an economic world. We do not understand that Mr. Thomas J. Grier, the superintendent of the Homestake, has received from the union intimations of any other purpose than that of excluding non-union men from the payroll. No standard of efficiency is proposed; submission means that no man may be discharged without raising ugly questions with the committee of the 'local'. As Mr. Grier well said, "The Homestake sees in this a strained effort to completely unionize this camp, a desire on the part of those responsible for the movement to take from the company the control of its own property." That is what the demands of Mr. Moyer's Western Federation of Miners have always meant. The Homestake is one of the greatest mines in the world; it has been operated for over thirty years; most of that time under the direction of the present superintendent; and this is the first clash

it has had with its employees. After such a record of cordial relations with the laboring man it will be hard to convince the public that the company has suddenly grown perverse and has dealt unjustly. Being a camp of large proportions, in which unionism had not become triumphant, the Homestake alone employing over fifteen hundred men, it represented nearly virgin soil for the Denver clique that controls the Federation. It meant the possibility of a large sum from initiation fees, and continuing revenue. The times were prosperous, and men were not clamoring for work. Moreover the crude distorted socialistic principles which have been applied in the Western Federation involve a pending strike in some quarter as *prima facie* evidence of performing a useful function for its members. It must be 'doing something' to demonstrate a reason for existence, and, in the narrow conception of the Denver ring, that means to be engaged in a war with capital. We hope the time will soon come when the Federation will be directed by wise counsels, and emulate some of the Eastern unions which have discovered that prosperity necessitates actual community of interests between employer and employee. Not long ago the Illinois branch of the United Mine Workers of America was represented on a powder commission appointed under agreement between the operators and the miners to settle all disputes relating to the use of powder underground; and still more recently a commission to revise the mining code of that State has been created by an Act of the Legislature which requires the appointment of three miners, who would necessarily be members of the union, three operators, and three disinterested persons. In Indiana some time ago fifty-two members of a miner's union were expelled for bringing action in a matter of a fine assessed against them for causing a 'stampede strike', and the union, as an organization, paid the fine which was levied under the terms of the contract. This shows what unionism may become as a responsible combination of workingmen. There must always be a *quid pro quo*. The ends of society are subserved by interacting helpfulness. To draw another lesson from the wise co-operation of labor and capital seen in Illinois, we may call attention to an adjustment of difficulties whereby Association mines employing union men are guaranteed the right to employ non-union men if they desire, this being understood to be a mere protection against charges of conspiracy, since the union men were conceded the right of not working with non-union men. When labor unions recognize mutual responsibilities, so that operators find it profitable to maintain close contract relations with them, and when States seek their advice in revision of the laws, a field of usefulness is revealed which has never yet been suggested by Mr. Moyer's personally conducted Federation.

A strike must be for the rectification of wrongs in order to win public sympathy. There is no appeal to the general conscience in a mere demand for unionization of a camp. The company must be shown to have failed in its duty somehow, and this has not been alleged in any utterances by Mr. W. E. Tracy who was sent from Denver to attend to the tithe-gathering at Lead City. The Homestake company

has enjoyed a long career of honest mining for the profit there was in it. The insiders have held their stock and have taken their dividends. They have never gone into the market to shear the lambs and make the public help to cover temporary financial difficulties. The opportunities thus to play the market have been many, but the Homestake has been conducted on conservative lines after the manner of any reputable business enterprise. It commands the confidence and respect of the people, and the union will have to assume a new rôle in order to win sympathy in its unprovoked demand for recognition.

Outcrop of Orebodies.

Prospecting as an industry avails itself but little of geologic knowledge. In districts where important mines have led to careful investigation of the geology of the ore deposits advantage has been taken of the facts thus ascertained, but only in a broad and general way have the lessons learned in one district been applied in the prospecting of new regions. This is partly because conditions at one place, superficially similar to those existing at another, do not necessarily involve the accompaniment of workable deposits of metalliferous ores. A number of notable failures have been made where geologists have undertaken to predict the presence of metals from surface indications. It must be recognized that such predictions can be based only upon analogy, and analogy is not proof. It here lacks the value of an essential relationship between vein enrichment and petrographic conditions. On the other hand, relationships do exist which enable trained observers to declare definitely in favor of or against the probabilities of the presence of ores, and these are revealed by the outcrops of veins and their associated country rock. In this view the highly suggestive paper concluded in this issue on 'Outcrop of Orebodies', by Mr. William H. Emmons, one of the younger men of the Geological Survey, recently called to a professorship in the University of Chicago, will be exceedingly welcome. It is the most thorough attempt yet made to generalize upon these phenomena. A most significant point is the topographic expression of lode-deposits. Veins which outcrop prominently, by virtue of superior resistance to erosion, offer no difficulty, but even in regions of acid eruptives, and where silicification of a lode has been a feature in its formation, the vein is not always harder than the enclosing rocks. The great majority of orebodies weather more rapidly than the country rock, and hence occupy depressions on the surface, or remain entirely inconspicuous except when indicated by the presence of characteristic alteration-products. Since pyrite is almost invariably present in ores of gold, silver, and copper, the traces left by its oxidation become of prime value, and these phenomena have been well set forth by Mr. Emmons. He has not, however, dwelt at much length upon the alterations of the gangue minerals in lodes.

Deductions as to the character and size of deposits from their outcrops are eminently risky. The aim of the geologist is naturally to see as deeply into the ground as possible; that is what the laity expect and what, in some degree, it demands as a measure of the worth of the economic geologist. To encourage such

expectations is, however, unfair both to those within and to those outside of the profession. The genesis of every deposit has its own peculiarities; each has its habit and characteristic geologic association, dependent upon the chemical relations of the surrounding rocks and the media whereby the metals were brought into their present position. It is in the diagnosis of the case as revealed by a study of the patient that the geologic doctor can point the way to successful development and save the expense of blind and futile groping. We commend the effort of Mr. Emmons, and of all geologists, to render prediction more trustworthy, but we are sceptical as to the wisdom of attempting to declare whether a vein will be deep or shallow, wide or narrow, reasoning only from hints given by its outcrop.

Aside from the main question of outcrops Mr. Emmons has been led to consider the means whereby gold may have been removed from or concentrated in the upper portion of veins. The little that is known of these processes, and the failure of geologists to clarify their discussion of them by chemical equations, may serve as another argument for the need of a research-laboratory under the auspices of the United States Geological Survey, sustained by adequate appropriations. It is useless to attempt it with inadequate funds. But that is another story—one which merits the consideration of Congress, which needs only to be convinced of an economic necessity to appropriate money in generous fashion. Mr. Emmons has endeavored to draw conclusions from what is known of gold-reactions in vein alteration and erosion that may be tersely re-stated as follows: when gold veins contain appreciable amounts of manganese, accompanying placer deposits need not be looked for; and where manganese is absent the gold is eroded with the rocks and enriches the gravels. We do not know of any important cases to the contrary, and the deduction is of economic value to the searcher after mineral wealth. Just how the gold is dissolved and carried beyond reach of denuding agencies in manganeseiferous veins is not precisely demonstrated. Solving the problem would throw light on other probabilities. Gold is slowly soluble in ferric chloride; moderately soluble in all ferric and cupric salts; and quite readily soluble in mixtures of the latter with ferric chloride. It is also readily dissolved by sulphuric acid in the presence of manganic acid (H_2MnO_4), which occurs in nature as the mineral manganite. In the oxidation of pyrite, marcasite, and pyrrhotite, a portion of the sulphur separates as sulphuric acid. Reagents for accomplishing the solution of the gold are consequently seen to be present. Whether the gold enters the solution as a sulphide or an oxide is of interest, particularly in view of the fact that apparently it always precipitates in the metallic form. Knowledge of the entire cycle of reactions is needful in order to admit of predictions as to the conditions under which re-deposition may be expected. The article by Mr. Emmons is full of suggestions which should awaken generous constructive criticism from students of economic geology. The world needs all the light it can get upon interpretation of outcrops, to the end that prospecting may be conducted in a less haphazard manner than in the past.

OUTCROP OF OREBODIES.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM H. EMMONS.*

(Continued From Page 754.)

Outcrops of gold deposits. Gold deposits undergo important changes at the surface of the earth. The work of Doelter, Becker, Stokes, Lenher, and others indicates that gold is dissolved by concentrated solutions of many salts which are found in earth-waters, but in the main at temperatures near or above the boiling point of water. Reactions under such conditions cannot have been important in changing outcrops of gold deposits, for the maximum temperature at which the reactions take place is known to be about room temperatures, and the pressures do not greatly exceed 15 lb. per square inch. Ferric sulphate, which is usually present in mine-waters, does not dissolve an appreciable amount of gold at or-

cess goes far enough it may result in depletion of the metal. This depends upon the rate of solution of the mineral components of a gold deposit. Take the commonest type composed of quartz, pyrite, and gold, the precious metal being contained as free gold in both the pyrite and quartz. As this ore weathers, pyrite is broken down first through oxidation. The sulphur and some of the iron are carried away as iron sulphate. The amount so removed is considerable. In the Granite-Bimetallic mine it is 0.6 of a ton every 24 hours. But a large part of the iron remains behind as limonite. Silica is dissolved and carried away, as is also the relatively insoluble limonite. Gold may be dissolved if chlorides and manganese are present and to some extent in their absence. If gold is not dissolved there is enrichment due to the removal of other constituents. If it is dissolved in greater proportion than the base elements, the outcrop is impoverished. The rate of solution of gold, and consequently the depth of the leached zone, and

the presence or absence of associated placers, depends upon the size of the gold particles, and probably to a considerable extent upon the presence of manganese oxide in the oxidized ore. Lindgren, comparing the Mesozoic gold deposits of the Pacific Coast and elsewhere with the gold deposits associated with the Tertiary eruptions⁴, notes that important placers have been derived from the former, and that the Tertiary deposits of the Great Basin and elsewhere have contributed but little placer gold. The gold, being in a more finely divided state in the late Tertiary deposits is more readily dissolved, or is more likely to be carried away.

In the Philipsburg quadrangle, Montana, I have had an opportunity for examining two types of gold-bearing deposits within a relatively small area. In one of these (Granite-Bimetallic lode), the gold is fine,

and considerable manganese carbonate is present in the primary ore. This, oxidizing, gives a notable amount of chocolate-colored manganese oxide, which is present in nearly every outcrop and in the oxidized zone to considerable depths. There are no placers associated with these deposits, and the outcrop carries less gold than the lode at a depth of 50 to 200 ft. below the surface. In the other type of deposit (Cable mine), gold is for the most part less finely divided, and manganese oxide is entirely absent or extremely rare. These deposits yield rich placers and they have been stoped to the surface. The leached or impoverished zone varies from nothing to 50 ft. and begins rarely more than 30 ft. below the surface. In the Comstock lode, which has yielded many millions in gold, but no relatively important placers, much manganese oxide is found in the upper levels. According to King⁵, "A zone of manganese oxide occupies the entire length of the lode from the outcrop 200 ft. down." Tonopah, Bullfrog, and many other camps in Nevada, may be cited as examples where there are no rich placers, and

(Photo., Ransome, U. S. G. S.)

dinary temperatures, but if ferric chloride is present also, and especially if manganese oxide is present, gold is dissolved much more readily, as has been shown by a number of investigations, among them Don, Rickard, and Lenher. Native metals, oxides, soluble reducing salts, and some forms of carbonaceous matter, are known to precipitate gold from the above solutions. Indeed, of all the commoner metals, gold salts are the least soluble, consequently gold is difficultly dissolved and easily precipitated, and so gold does not travel far below the outcrop, and consequently the zone of leached oxides vertically is not extensive. There are no examples of gold deposits of proved secondary enrichment which are at all comparable in size and richness to the secondary sulphide deposits of silver and copper. It is not uncommon, however, to find the richest part of a gold deposit just at the surface or more often just a few feet below the surface and extending downward to the bottom of the oxidized zone. The process of oxidation is at first one of enrichment³, but if the pro-

⁵'Fortieth Parallel Exploration', Vol. 3, p. 75.

where a notable amount of manganese oxide is present in the oxidized ore. In these camps, as a general rule, the outcrop, and a shallow zone below, carry less gold than the deeper oxidized ore. The same statement may apply to the Granite Mountain lode, in Montana, and to the Butte deposits. At first glance the latter seem to be exceptions to the gener-

Fig. 8. A Quartzite Lode in Altered Andesite, Valley View Mine, Tonopah, Nevada.

The outcrop and open-cut show in the foreground.
(Photo., Spurr, U. S. G. S.)

alization that manganese is unfavorable to the formation of placers and favorable to leaching, for there is considerable manganese in the Butte veins, and yet the camp was first exploited for its placer gold. As is well known there are three periods of mineralization shown by the Butte deposits, and the deposition of rhodochrosite seems to be limited to the deposits of one or possibly to two of these periods. The small amount of placer gold which has been won at Butte may well have come from the manganese-free deposits. On the other hand, the placer-yielding lodes of the Pacific Coast carry little or no manganese oxide and this circumstance may be responsible to some extent for the great accumulations of placer gold and the small amount of leaching which the deposits of this class have undergone. In general, coarse gold and freedom from manganese are favorable to the enrichment of placers and are unfavorable to the leaching of the upper part of the oxidized zone. Consequently shallow exploration, usually not more than 50 ft. in depth, is sufficient to prove the value of a deposit of this character, providing the work is done on an ore-shoot. Finely divided gold, and the presence of manganese oxide, are unfavorable to the formation of placers and are favorable to leaching of the upper part of the oxidized zone, but this does not seem to take place to any great extent much lower than 100 ft. below the outcrop of the deposit, but where there is considerable fissuring, and the ground is open, leaching of gold may extend to greater depths, and in such places it may be necessary to sink deeper to be sure that the leached zone has been passed, but for mines where gold is the only important metal sought, 200 ft. in depth seems a safe figure.

Recent inspection of a large number of stopesheets of gold mines indicates that even where gold is finely divided, and manganese is present in the veins, the majority of outcropping orebodies are

stopped to less than 50 ft. from the surface. Briefly stated, in the average gold deposit, which outcrops at the surface, the workable ore is encountered at the surface or within 25 or 50 ft. of the surface, but in some cases it is found 100 ft. below the surface, and exceptionally, 200 ft. below the surface, depending upon the fineness of the gold particles, the presence of manganese dioxide, and the amount of post-mineral fissuring.

Outcrops of silver deposits. Most silver minerals are readily dissolved by surface-waters, and the leaching may at some places extend to greater depth than the leaching of gold. Silver enters into the composition of a great many minerals, chief of which are the native metal, the halogen compounds, the sulphide, the sulph-arsenic, and sulph-antimony compounds. Silver is also contained in the sulphides of the other metals, especially in galena, pyrite, and zinc blende. A large proportion of the silver ore is of this character. At 18°C. in pure water silver salts have the following order⁶ of increasing solubility: I. Br. Cl. CO₃. C₂O₄. OH. SO₄. ClO₃. NO₃. F. The solubility of the sulphate is 0.55 grain in 100 c.c., or nearly three times the solubility of gypsum, which is commonly regarded as a soluble mineral. The silver sulphate is formed by the oxidation of the sulphide and other silver compounds or by the action of ferric sulphate⁷ on silver compounds. This reac-

Fig. 9. Outcrop of Drinkwater Vein, Near Silver Peak, Nevada.
(Photo., Spurr, U. S. G. S.)

tion takes place at the lower temperatures, and therefore may be important under the conditions at which silver ores are exposed to agents of weathering. Accordingly in the presence of sulphate-waters silver minerals are readily dissolved and carried away in solution. The sulphates in solution may be

⁶As measured in moles per litre, determined by Kohlrausch by the conductivity method.

⁷H. N. Stokes, *Econ. Geol.* I, p. 649.

reduced by sulphides* of Cu, Pb, Fe, and Zn, in which case the silver will form a secondary sulphide which is relatively insoluble and easily precipitated, or if it is not precipitated it may be carried away from the deposit in the general underground circulation.

The chloride of silver is relatively insoluble. At 18° only 0.0016 grain will dissolve in a litre of pure water, which is a small fraction of 1% of the amount of silver sulphate which is so dissolved. On account of its comparative insolubility the chloride, horn silver, will be precipitated from silver sulphate solutions in the presence of chlorides. Being relatively insoluble in earth-waters it is not easily removed, and so at many places it is present in important quantity at the very outcrops of silver-rich orebodies. As pointed out by Penrose⁹, silver chloride forms extensively in the upper part of silver-rich orebodies in the arid regions of the United States, especially in the Basin province. The earth-waters there carry much chlorine owing to the poor drainage as a result of which salt lakes and marshes have formed at many places. It is well known that salt is vaporized in sea water, just as H₂O is vaporized. It is carried down to the earth in the rains, and there is a continual circulation of NaCl from the ocean to the land and back to the ocean, just as there is a circulation of H₂O. Although the salt circulates in very small quantities, the amount is quite sufficient to form important bodies of silver chloride. The effects of the circulation are shown 100 miles inland from the sea,¹⁰ and so within 100 miles of a body of salt water we may expect to find the chlorine in rain water. Further, there is residual chlorine in some of the sedimentary rocks, and so the conditions for the precipitation of the chloride may hold at places far removed from salt water. The abundance of chloride formed is not in direct proportion to the salt present in earth-waters even when other conditions are constant, for silver chloride dissolves in an excess of the alkali chlorides, and the presence of too much salt will cause the chloride to re-dissolve and be carried away from the outcrop. Perhaps this is the reason that some silver chloride deposits are a little richer a few feet below the surface than at the outcrop. However that may be, there is a strong tendency to concentration at or just below the outcrop of the silver lode, and this is most marked in arid regions, so much so that the word 'chloriding' was very generally used in such regions for pocket-hunting near the surface in the early days of mining in the Great Basin States.

Native silver, like the chloride, is often found at the outcrop of the lodes. In nearly all deposits of the western Cordillera it is clearly the reduction-product of the sulphide, chloride, or other silver salt. Spurr, in a recent article¹¹ emphasized the abundance of native silver and the absence of ruby silver at Aspen, Colorado, where shale often forms one of the walls of the deposit. At Georgetown and other

campes near by, the ruby silver is a common and sometimes abundant secondary mineral, and the native silver relatively rare. The complete reduction of the silver salts to the native metal has here been accomplished by the shale which is rich in carbonaceous reducing agents. Native silver may, however, occur in considerable quantities in oxidized ore where no shale is present, as in the Granite-Bimetallic lode in Philipsburg mountain, and in a great many other silver lodes. The commonest type of the rich silver outcrop is composed of spongy iron-stained quartz plastered with horn silver, and carrying thin flakes of native silver. Pyromorphite, the lead chlor-phosphate, often carries silver and in Montana, Colorado, and Nevada, this mineral frequently appears in the outcrop. Silver bromides and iodides form to some extent. In pure water at 18°C., these silver salts are less soluble than the silver chloride. But since bromine and iodine are much less abundant than chlorine, the iodide and bromide of silver are not common. I have made a large number of tests of suspected bromides taken from outcrops in Montana and Nevada, and have never had a satisfactory test for bromine in any of them. The law of mass action enters here, and accordingly the halogens other than chlorine play a subordinate role in the outcrops of most silver lodes.

There are many shoots of silver ores which are not everywhere workable at the surface, and in some of these the chloride is among the silver minerals. Notwithstanding the relative insolubility of this mineral, and the general presence of chlorine in earth-waters, some of the outcrops of silver lodes are leached to a considerable depth below the outcrop. Characteristically the oxidized zone may extend from the surface to the level of the ground-water, or slightly below this level, depending largely upon the fissuring to which the ore has been subjected. In the Comstock¹² lode this oxidized zone extends in places 500 ft. below the surface, whereas at other places the sulphide continues to the surface. In the Granite and Bimetallic mines incomplete oxidation has taken place deeper still, and in the Mizpah mine, at Tonopah,¹³ some oxidation extends to a depth of 700 ft. In all of these mines the bottom of the oxidized zone is irregular, depending largely upon fracturing, and in all of them leaching seems not to have taken place to any great extent below the middle of the zone of oxides. Inspection of a number of stope-sheets of silver mines shows that most silver lodes are at some place workable at the surface; but that there is also a fairly constant horizon from 75 to 200 ft. below the surface that represents the top of the zone of workable ore. In some mines where there has been considerable fracturing of the ore since it was deposited there has been some leaching locally as deep as 400 ft. below the surface, but this depth should probably be regarded as near the maximum for silver deposits. Leaching seems to have been important on the average less than 200 ft. below the surface and unless the ground is open and the circulation very free the oxidized ore-shoot should be payable at that

depth. If an important proportion of the metals is gold, the workable ore should be expected nearer the surface than in ore where the gold is a relatively unimportant constituent.

Galena is, as already stated, less readily decomposed than pyrite, zinc blende, and antimony sulphides, and it, therefore, lingers longer in the outcrop. It is dissolved, however, for it does not usually occur in great abundance immediately at the surface, but is often found a few feet below. In Wisconsin many lead deposits have been discovered by farmers who were plowing fields and in the Coeur

the outcrop where the rock is tight. These deposits often are found at the surface, the native copper outcropping with the rock, only slightly tarnished or altered to oxides or carbonates. Where the rock is open, there is some leaching of the outcrop, but most of the deposits of this group may be worked to near the 'grass roots'.

Most of the schistose ores in regionally metamorphosed igneous and sedimentary rocks are in the Appalachian States. They are probably the regionally metamorphosed products of ores of varied character, including the fissure veins, magmatic segregations, and replacement deposits. They are, as a rule, tight and not greatly affected by movement since they were formed, consequently, they are not leached to great depth, and the primary sulphide ore usually appears at less than 100 ft. below the surface. In the Northern States where the deposits have been glaciated, the primary sulphides usually outcrop at the surface, and even where there has been some crushing the oxidized zone does not usually extend more than from 5 to 25 ft. below the surface. In the Southern States, where there was no Pleistocene glaciation, this zone extends to greater depths, and at Ducktown it is fairly uniform, and from 30 to 50 ft. deep.

The second important group of copper deposits is mainly, if not altogether of Mesozoic age, or else the earliest Tertiary. This group includes ten of the thirteen leading copper camps of the United States. In all of these the igneous rock associated with the ore deposits is diorite or the porphyritic equivalent, or a rock which is more acid. In at least eight of these camps, and probably in all of them, there has been con-

Fig. 10. Outcrop of Large Lode, Four Miles Northwest of Globe, Arizona.

(Photo., Ransome, U. S. G. S.)

d'Alene, Idaho, at Eureka, Nevada, and at Bingham, Utah, some silver-lead deposits were worked from open-cuts. Compared with the silver ores which are rich in arsenic and antimony minerals, the silver-lead deposits are less readily leached of their metal content, and for that reason the workable ore may be found nearer the surface. With respect to shoots of silver ore which do not outcrop, no generalizations can now be made. The leaching of these presents a wider range of possibilities, and, as a rule, no seemingly rational interpretations may be made.

Outcrops of copper deposits. The important copper deposits of the United States fall into two large groups. First, deposits in regionally metamorphosed rocks which are associated with granite-gneisses, diabase, actinolite, schists, and other basic rocks, or which occur as lenses in quartz-biotite schist, quartz schist, and related rock, and, second, deposits of Mesozoic age or early Tertiary, associated with monzonites, granites, their porphyries, and similar rocks. There are no middle or late Tertiary copper deposits in the United States comparable to the silver deposits of that age, just as there are no silver deposits comparable to the pre-Cambrian and Mesozoic gold and copper deposits.

The first group, which is in the main pre-Cambrian or Cambrian, includes the Lake Superior deposits, and the Appalachian deposits of pyritic copper ore, of which Ducktown is the most important example. Of these, two principal types may be recognized. They are (1), native copper in vesicular basalt or diabase; (2), schistose ores in regionally metamorphosed igneous or sedimentary rocks.

The native copper ore in pre-Cambrian conglomerate, basalt, or diabase, are not greatly leached at

Fig. 11 Outcrop of and Workings in Copper Ore Disseminated in Porphyry, Bingham, Utah.

(Photo., Boutwell, U. S. G. S.)

tact-metamorphism, and the development of garnet zones in connection with the intrusion, but in few, if any, is the ore of the garnet-gangue of the first importance. Several types of these deposits may occur in one mining district. The most important classes are:

(1.) Garnet zones with sulphides intergrown with contact metamorphic silicates.

- (2.) Replacements of limestone.
- (3.) Fissures in granitic rocks.
- (4.) Disseminated chalcocite ores in monzonite porphyry.
- (5.) Chalcocite ores disseminated, and in sheeted zones in quartz-muscovite-biotite schist.

The garnet zones outcrop rather boldly as a rule. They alter to limonite, turgite, hematite, kaolin, and other minerals, forming a gossan not unlike a gossan of pyrite in some respects, but weathering is not so rapid. In these zones are often seen bunches of carbonate, oxide, or even sulphide copper ore, directly at the surface, though at some places there is leaching to a depth of 25 or even 50 ft. Not often is there leaching to greater depth. The bunches of rich oxidized ore which at some places are found in the outcrops of the garnet zones probably result from the oxidation of secondary chalcocite ore. Nearly everywhere the garnet zones are worked by open-cuts, a fact which illustrates the superficial character of their leaching.

Examples of garnet zones worked by open-cuts are several of the mines of the Clifton-Morenci group, described by Lindgren in his monograph on the district. Some copper deposits at Bullion, Nevada, also are stoped at the very surface. The Holland and other mines in the Patagonia district, Arizona, according to F. C. Schrader, belong also to this class, with which may be included the majority of garnet zones.

Replacements of limestone are so irregular in shape that no comprehensive statement can be made with respect to the depth of their oxidation. Many of them do not outcrop at all. The Copper Queen at Bisbee, which is the greatest mine of this group, outcropped only at one point and then was stoped at the surface. On the other hand, the tops of some other deposits at Bisbee and of other portions of the Copper Queen deposits are too low in grade to work, while the lower portions are bonanza chalcocite ore.

In regions of copper-rich magmas, and especially in zones of actively descending solutions, it would be poor prospecting to abandon a large limonite body in limestone at any depth short of several hundred feet, and not then unless the associated sulphides were known to be barren.

Fissure veins in deep-seated igneous rocks include the Butte and the Corbin deposits in Montana, and some scattered mines in other districts. If these veins are strongly fissured since the first filling (and the best of them are), then the copper is carried down 200 or even 400 ft. below the surface. This depth is greater also in areas of abundant groundwater, such as Butte, where of all copper lode camps of the United States the leached zone is greatest. The veins usually outcrop as iron-stained quartz, yellowish brown or red, or, when manganese is present, they are chocolate brown to black. Some are stained with copper carbonate, but they carry little copper at the surface, not much silver, and but a small amount of gold.

The disseminated copper ores in porphyry are perhaps the most important group of copper deposits. They are nearly everywhere of low grade, running from $1\frac{1}{2}$ to 3% copper, but they are so

large that they can be mined cheaply, and the mineral composition of the ores is such that they may be concentrated cheaply and with a fair saving. They are found at Bingham, Utah; Clifton, Arizona; and Ely, Nevada, and have been described by Lindgren, Boutwell, Lawson, Tolman, and others. At all of these camps they are inclosed in deep-seated intruding porphyries, the composition of which has a narrow range from a rather acid diorite to a rather calcic granite. At each of these camps the intruding porphyry broke through limestone, and in every case it had the power of inducing contact metamorphism. In all of these camps garnet zones with copper-bearing sulphides were developed in the limestone, and at every camp these have been rich enough to work, but, with the exception of the deposits in the Clifton-Morenci district, the value of the garnet zones is small compared with the deposits in the porphyry itself.

The porphyries which are responsible for these deposits were probably intruded in the same general period of vulcanism. At Clifton, Mr. Lindgren found that the intrusives cut the Pinkard formation, which is of Cretaceous age, and he regards the age of the intrusive as late Mesozoic or very early Tertiary. At the other camps Mesozoic or early Tertiary sedimentary rocks have not been found in contact with the porphyry, but from broad considerations it is highly probable that the ore-bearing magmas were intruded into the sedimentary rocks in the late Mesozoic, at the very beginning, during, or at the close of the Cretaceous. The deposits themselves show many points of similarity. All of them are formed in zones of fracturing, sheeting, or fissuring, but wide fissures are rarely developed. The country rock is always highly sericitized, but rarely or never contains carbonates. At all of the camps except Bingham the sericitization of the porphyry is so intense that great areas have been converted into a white monotonous rock that in hand specimens gives but little evidence of its true character. It is a difficult task to work out the genesis of these deposits, and it is only on their outer edges where the action has been less intense that their history is shown. Probably a small proportion of the original sulphides consolidated with the rock minerals from the molten magma, but most of the primary ore was formed just after the solidification and the shattering of the country rock, and the solutions were contributed by the still liquid portion of the eruptive below. This is shown by the character of the hydrothermal metamorphism. The ore was deposited in the fractured, shattered, and sheeted zones, and to some extent through replacement, the metals being deposited as sulphides along with the potash which was deposited as sericite. Workings in the ore-bearing monzonite at Bingham, Utah, are shown in Fig. 11.

At favorable places these orebodies have been fractured, sheeted, or fissured, and where this has taken place descending waters dissolving the upper portions of the orebody have deposited chalcocite ores lower down. Some of this chalcocite is massive, but a large part is merely in films on the primary low-grade pyrite and chalcopyrite. The depth to which such chalcocite enrichment descends is seldom

more than 600 ft. below the surface, and it often ceases before that depth is attained, but in exceptionally open rocks it may be deeper. The depth to the pay ore, which consists either of the chalcocite or of oxidized chalcocite (carbonates, oxides, and native metal) varies, but usually within rather narrow limits for a given district. At Bingham there is from 50 to 100 ft. of low-grade unworkable rock above the better ore. At Clifton this zone is, according to Lindgren, from 100 to 225 ft. deep. At Ely, according to Lawson, it reaches a maximum of 500 ft. The last figure is exceptional, however, and probably may be explained by unusual conditions.

The outcrop of these deposits is always strongly leached, and the sericitized feldspar is usually highly kaolinized by surface waters. In color some of the outcrops are almost white, but nearly everywhere they are stained with iron, and then their color varies from lemon yellow to reddish brown, or, in the more arid countries, to brownish black. Some stains of copper carbonate and copper oxides may be found at the surface, but at many places these are not present even over good deposits of chalcocite ore. The outcropping country rock is usually so highly altered that its constituent primary minerals are beyond recognition in hand specimens. As a rule, the dark minerals are removed entirely, but some biotite may remain where hydrothermal action has been less intense, and to some extent it may be dissolved by hot waters.

Briefly stated, then, it is warrantable to look for these deposits in deep-seated porphyries of Mesozoic age, in the acid diorites or still more acid rocks, and these are extensively developed in the central Cordilleran province, in Sonora, Arizona, Nevada, Utah, and in Idaho and Montana. They are to be sought in the silicious and especially in the potash-rich portion of the eruptives, or in the highly sericitized portion. They are in zones which suffered fracturing shortly after solidification, a large number of small fractures being the more favorable condition for extensive deposition. They are richest where shearing, fracturing, or shattering has taken place since mineralization, permitting a downward movement of water and the deposition of chalcocite. The outcrop is marked by iron-stained sericitized rock, seldom with conspicuous phenocrysts, varying in color from lemon yellow to a dark brown, and rarely showing much copper at the surface. They are of workable grade at depths varying from 15 to 250 ft., and the workable ore may extend downward to 500 or 700 ft. below the surface. They are in areas of copper-rich magmas, in areas of contact metamorphic copper ore, of copper-bearing fissure-veins, or replacement deposits in limestone. Although the most important, they are seldom the only type of deposit represented in the district.

The chalcocite ores disseminated and in sheeted zones in chlorite, biotite, muscovite schists are the last great group to be developed. All of the important deposits known of this class are found in Arizona and in the Pinal pre-Cambrian schist. They include the Miami deposits at Globe and the recently developed deposits at Ray, Arizona, the Ray Consolidated, Gila, and Ray Central. These schists which are

metamorphosed quartzitic sediments, according to F. L. Ransome,¹⁴ are abundantly exposed in the Pinal mountains, where they are cut by many intrusives of granite, diorite, and other eruptive rocks. At Globe the intrusion is so intimate that it is impractical to separate the schists from the eruptive rocks on a map of usual scale. According to Ransome, "the brecciation of the schists probably dates back to an early period. At that time the schist laminae were crumpled and broken, presumably under a slight superincumbent load, and the open or lenticular spaces were filled with quartz. The result was a fragile rock, full of small surfaces of weakness, that was thoroughly shattered by later movements." Some veins and zones of fault-breccia cut across the planes of schistosity, and the ore surrounds the breccia fragments, indicating that the mineralization is later than the regional metamorphism. The age of these deposits is probably Mesozoic. They may be contemporaneous with the disseminated ores in porphyries with which they seem to have many points in common. The Schultze granite, which may be responsible for the mineralization, is, according to Weed, Spurr, and Tolman,¹⁵ post-Paleozoic (Tertiary?) in age, and intrusive in the Pinal. The schist is impregnated with chalcopyrite, and contains numerous small veinlets of ore. The chalcopyrite is enriched by chalcocite. There is some leaching at the surface, but exact figures giving the depth of the leached zone are not now available. At Globe the oxidation in the schists is, according to Ransome, much more shallow than in the deposits in limestone, in quartzite, and in other rocks.

Change of state, from gas to liquid and solid, or the reverse, involves either an absorption or a liberation of energy. In most instances a change from one state to another is accompanied by a marked difference in mobility of the molecules of the substance. In such cases the energy absorbed or liberated is an appreciable quantity, often considerable; and when it is expressed, or measured, in units of heat the temperature at which the change takes place for given pressure is definitely determinable. But when there is no marked difference between one state and another, as when a solid upon increasing temperature passes through imperceptible gradations from a slightly plastic solid to an equally viscous liquid, there is no appreciable quantity of heat absorbed at any particular temperature, and consequently no definite melting point.

Heavy stamps have the following advantages over light ones, according to W. A. Caldecott: reduction of the initial capital expenditure in erecting, say, 200 stamps of 1750 lb. in place of 280 at 1250 lb. to do equal duty; reduction in size of mill-building, which varies almost directly with the number of stamps; reduction of power transmission equipment, which is nearly 30% less; and a lessening of labor cost, lubrication, and time losses, which also represents a difference of about 30% in the case cited.

STRIPPING A VEIN BY HYDRAULICKING.

Written for the MINING AND SCIENTIFIC PRESS
By A. F. HUGHES.

An interesting method of uncovering ore has been devised and successfully used by the management of the Trinity Gold Mining & Reduction Co., at its properties near Carville, in Trinity county, California. With the hope that a description of the method and the conditions governing its application will be of benefit to others of the mining profession I have gathered the following data regarding it.

At Beginning of Operations. Looking West.

The ore is essentially a gossan, derived from a heavy iron sulphide, containing generally: Fe 29%, S 30, Si 18, and small percentages of Cu, ranging from 0.5 to 2. Only traces of Cu appear in the gossan, that metal probably having been leached out during the oxidation of the original sulphide. The orebody may be described as a replacement vein dipping at an angle of about 23° to the northwest, and lying between a hanging wall of slate, and a

Ore Uncovered by Sluicing.

foot-wall of quartz-porphry. On account of the selective action of replacement, both walls are quite irregular, and the porphyry is often found as part of the hanging wall. After the primary orebody was formed there was a period of intense faulting and brecciation. The entire orebody, together with the adjacent country rock was cracked and broken. Both then being in a condition which permitted of easy percolation, began to be changed; the one by oxidation and the other by decomposition. The sulphide became cemented by its own product of decomposition. Hand specimens show, in fresh fractures, the forms of the original fragments. The soluble ingredients of the porphyry, especially of

that overlying the sulphide, were leached out, leaving the residual material in a soft and plastic condition.

From all obtainable sources, which included tunnels and cross-cuts under the ore, a number of shafts from the surface, raises through it, and an extensive exposure of croppings, the vein was estimated to have a perpendicular thickness between walls of 30 ft. or more, and to contain approximately 200,000 tons of millable ore. From the first it was evident that to make the venture a profitable one it would be necessary to exercise the utmost economy in mining the ore. Except for the presence of the hanging wall, varying in thickness from nothing up to 50 ft., mining could be carried on ideally by the open-cut method. To make that possible, and to prove more conclusively and quickly, the extent and continuity of the orebody, the management determined to strip the overburden by the use of a hydraulic giant, using 300 cu. ft. of water per minute, working under a head varying from 300 to 350 ft. The giant was supplied with a 2½-in. nozzle. The necessary water for this operation was easily available, since the company owns a water right, together with a ditch whose terminus is not over 700 ft. distant from the deposit.

The work was commenced near the croppings on

Uncovered Ore Below Stream; Overburden Beyond.

the west and carried on toward the rising ground to the east, where the overburden became thicker—up to nearly 50 ft. in places. At the beginning, trenches were cut by the stream along the dip of the deposit. It was found expedient to help the giant in making the bottom cuts, by blasting in lines radiating from the nozzle. It was never necessary to blast the bank, as it always caved when a good undercut was made. Generally from eight to ten 6-ft. holes, placed about seven feet apart, were fired at a time. The holes were all driven with augers, the softness of the porphyry permitting their use. The augers used were not of the common type of double-pointed bit, but were made after the pattern of a machinist's twist-drill tapered off at the striking end, and fitted with a loose cross handle. Two men worked with each auger; one turning and the other striking. While at times some fairly tough ground was found, it rarely took more than 20 minutes to drive a 6-ft. hole. While the holes were being driven the giant was used in keeping the loose dirt moving down the gulch.

During the three months when there was sufficient water for sluicing, it is estimated that 150,000 cu. yd. of overburden was removed at a cost not to ex-

ceed \$2800. This means that the work was done for about 1.3c. per ton of ore. It is true that the work was carried on under more favorable conditions than might obtain in other localities. Nevertheless, it seems to me that the above costs were low considering the work accomplished. Some of the conditions tending to simplify were: (1) The drainage area of the Trinity river does not come under the regulations of the California Débris Commission, which makes it possible to let the sluiced material take care of itself. (2) The fall from the workings to the Trinity river was more than sufficient to carry the material sluiced, even to the size of three inches in diameter. (3) The decomposed condition of the porphyry overburden simplified to a great degree the sluicing operation.

OZOKERITE IN UTAH.

Written for the MINING AND SCIENTIFIC PRESS
By H. W. MACFARREN.

Ozokerite may be characterized as a mineral wax or paraffin occurring in veins in the earth, usually in the vicinity of bituminous and petroleum deposits. It varies in color from brown to black, and has the appearance and consistence of wax, spermaceti, or paraffin. Analysis gives approximately 85% carbon and 15 hydrogen. Its specific gravity is 0.85 to 0.90, and its melting point 50 to 70°C. The fact that it is lighter than water and melts at a lower temperature than water volatilizes, plays an important part in the process of separating the wax from the rock gangue with which it occurs. While ozokerite can be put to practically all of the uses to which paraffin is applied, being essentially a paraffin, there are some uses for ozokerite for which there is no substitute, such as in the manufacture of certain kinds of shoe blacking and insulating material, and making phonographic records. It is refined into ceresin to be made into fine candles, ointments, pomades, floor wax, and similar objects, or to be used as a substitute for beeswax.

It is found in paying quantities in two localities only, in Galicia in Austria and in Utah in the United States. The Gallician deposits have been and still are the principal source of supply. The wax occurs there in oil-bearing sandstones, shales, and sandy clays of the Tertiary age, as stringers of wax along the stratification of irregular fissures. The ore is mined by lessees working small blocks of ground. After sorting out the waste, the ore is boiled in water in kettles, the wax rising to the top and being skimmed.

As a result of the lessening yield of this field, the price of high-grade crude ozokerite has risen in late years from 6 to 16c. per pound. Ozokerite is found in the vicinity of Soldier Summit and Colton, Utah, on the Denver & Rio Grande railroad, 120 miles south of Salt Lake. It is noteworthy that it occurs here under the same geologic conditions as in far away Galicia—in shales, shaly sandstones, and limestones of the Tertiary period, and contiguous to great deposits of carbons and hydrocarbons. The wax is not found in the strata to the same extent as in Galicia, but rather in vertical fissures that cut the

strata. These fissures form shear-zones, one wall of which is usually perfect, while the other is coarsely broken or brecciated. The wax is found as sheets or films between the walls and as stringers throughout the brecciated mass for a few feet away from the main fracture. It also occurs permeating the ground-up mass. These sheets are usually a fraction of an inch in thickness, but have been known to widen to form pockets of wax two or three feet across. In the museum of the California State Mining Bureau, Ferry Building, San Francisco, is a sheet of wax three-quarters of an inch in thickness that was taken from a Utah mine by me, which shows the characteristic occurrence of ozokerite. These mineralized fissures are generally of great length, and it is presumed of depth also, but uncertain as to width and percentage of wax. At the surface, or where the wax has been exposed, it tends to brittleness, but away from the surface, where it retains more of its volatile substances, it is soft and

Map of Utah.

flexible, and can be picked out and chewed like a paraffin chewing gum. There is a tendency for certain constituents of the wax to ooze out and stain the surrounding rock. This, together with the fact that the wax is approximately three times lighter in weight than the gangue or wall rock is liable to lead to erroneous conclusions as to the percentage of wax in the ore. All evidence tends to the conclusion that this ozokerite is the residual product of a petroleum, having a paraffin base, and was forced into these seams and fissures; the lighter hydrocarbons being subsequently volatilized, leaving the less volatile matter, or wax, behind. The same compound has been obtained from bituminous substances by destructive distillation.

The metallurgy of ozokerite as developed in Utah is simple. The ore is crushed in a breaker capable of crushing to one-quarter inch. Coal crushers and Sturtevant rotary crushers have been used. The

crushed ore is fed by a belt-driven plunger feeder of simple type to a tank of hot water in which the wax is melted from the gangue. The first tanks were constructed of steel, and steam jacketed. Later they were built of 3-in. wood planking at small cost. These tanks are 3 ft. deep, 14 in. wide, and 25 ft. long. In the bottom of the tank are placed two 12-in. screw conveyors, each 12 ft. long, operating as one screw, with stuffing boxes at each end, submerged centre-bearing, and driving mechanism outside one end of tank. A 2-in. pipe carrying exhaust steam for heating the water runs along each side of the tank just above the screw. The tank is filled with water and the steam turned through the pipes, rapidly bringing the temperature of the water to 170 to 190°F. The screw is started at the rate of six revolutions per minute, while the ore is fed in at one end of the tank. As the melting point of ozokerite is about 130°F., the wax at once commences to melt and rise to the surface of the water.

The success of the operation just described depends upon the wax being entirely liberated from the rock during the short period of its conveyance from one end of the tank to the other. Arriving at the farther end of the tank, the tailing is either lifted out by an inclined screw or drops into a cone attached to the end of the tank, from which it is discharged intermittently by a quick-acting valve operated by hand; the tailing being too coarse to admit of the continuous discharge used in cone devices for dewatering tailing.

The wax was at first skimmed from the top of the tank into pans. After cooling and hardening, the earthy impurities which had settled to the bottom were chiseled off, when the cake was sacked for shipping. It was soon found that the cakes were not acceptable to the buyers because of bad condition due to the moisture entangled in the wax. This led to the perfection of a continuous method of refining. The wax is drawn constantly from the melting tank to a small steam-jacketed cone tank acting on the principle of a water-clarifying cone, the settled impurities being drawn off from the bottom. Steam coils are used in this cone to assist in keeping the wax melted and to drive off the entangled moisture. The melted wax overflows the cone to pass about more steam coils to further reduce the contained moisture, finally flowing into pans in which it is cooled to form cakes that are satisfactory. The capacity of one of these melting and refining units is from 25 to 50 tons of ore per 24 hours. The amount of coal required to heat the water and wax is remarkably small, so that the whole process may be said to be both efficient and economical.

About five plants for extracting ozokerite have been erected in Utah, resulting in the production of several hundred tons of wax. None of these are now operating. The reason that more has not been done is simple—no extensive bodies of commercial ore have been found. It is impossible to say just what percentage of wax the present known bodies contain, but it can be understood that with ozokerite at 16c. per pound f.o.b. New York City, 2% wax would be valuable. Prospecting for ozokerite is being carried on in many localities.

SEVEN TROUGHS DISTRICT OF NEVADA.

By F. L. RANSOME.

*The Seven Troughs district, which is about 30 miles northwest of Lovelock, a flourishing town on the main line of the Southern Pacific railroad, lies on the east slope of a minor range designated on the Fortieth Parallel Survey map as the Pah-tson mountains, but now popularly known as the Seven Troughs mountains, but occasionally referred to also as the Stonehouse range. The higher parts of the mountains are dotted with junipers and the larger ravines contain small perennial streams. Grass flourishes on some slopes and for over 30 years the region has been used as a range for sheep and cattle.

Map of Nevada.

The watering places maintained in connection with this pastoral occupancy have given to the new mining district its name.

Supplies are hauled by teams from Lovelock. Passengers may reach the district most conveniently from the same point by the ordinary stage line or by automobiles, which meet the transcontinental trains and ply over a little better road than is used by horse-drawn vehicles. There are four little towns in the district, three of which, Vernon, Mazuma, and Farrell, are situated at the east base of the range. Vernon, the southernmost of the three, was the chief settlement in the district early in 1908, but had lost its pre-eminence by August of that year, most of the activity then centering about Mazuma, 2½ miles north-northeast of Vernon, and about Seven Troughs, which is 1¼ miles west-northwest of Mazuma, higher up the same canyon. Farrell, three or four miles

*Abstract from Bull. 414, U. S. Geol. Survey.

north of Mazuma, has at no time been as important as the other settlements.

The Seven Troughs mountains have a length of 24 miles and trend 20° east of north. The greatest width of the range is eight miles. Its crest culminates in a group of three summits. These attain altitudes of about 3000 ft. above the desert plains that surround the range on all sides but the north. The highest and middle summit is Granite peak. The one southwest of it, of schist, is designated Pahkeah peak on the Fortieth Parallel Survey map. A low broad pass, occupied according to this map by Miocene lake beds belonging to the Truckee formation, separates the north end of the Seven Troughs range from the longer Trinity range and from the Kamma mountains, a small group within which is the Rosebud mining district and the Rabbit Hole sulphur mine.

The known ore deposits of the Seven Troughs range are all in the Tertiary volcanic rocks, and consequently a small part only of the four days spent in the district could be devoted to the older formations. North of Mazuma the so-called Jurassic rocks appear first in Burnt canyon as a northeast-southwest belt of indurated clay slate about half a mile wide. This belt appears to correspond at this place to a low ridge, which, after having been completely buried under lava flows, has been uncovered again by erosion. The slate extends northeast and forms the rounded foothills just west of Farrell. It was found to be exposed westward along Stonehouse canyon nearly to its head. The dip varies and the slate is cut by dikes of a light-colored rock, presumably rhyolite. Near the head of the ravine the slate is intruded and metamorphosed by the 'younger granites', described by Hague and Emmons.

The intrusive granitic rock at the head of Stonehouse canyon is a fresh, medium-granular, rather dark gray rock, which evidently is not very quartzose and contains a large proportion of plagioclase. The microscope shows the rock to be a granodiorite.

The prevailing rock of the low, rounded hills on the edge of the Sage valley at Mazuma, and for a mile or more up Seven Troughs canyon is a pale reddish brown lava, much of which shows conspicuous flow lamination and a platy fracture. The rock is not a rhyolite but, pending chemical analysis, must provisionally be classed as a mica andesite, unusually poor in femic constituents. Much of it is a mica andesite vitrophyre. Associated with the mica andesite, which appears to occur in several thin flows, is at least one flow of vesicular basalt, some of which is exposed on the slope just north of the west end of Mazuma.

Directly under the vitrophyric andesite there is, as a rule, a flow of basalt. The thickness of this is not known but appears to vary greatly. Under this basalt and occupying the bottom of the Seven Troughs amphitheatre is a volcanic complex of rhyolite, basalt, mica andesite, tuffs, arkosic sandstones, and possibly other rocks of which the structural relations are as yet imperfectly known and which probably can be ascertained only by careful mapping and detailed microscopic work.

The most important group of mines is at Seven Troughs. Just southeast of the town, which lies on the south bank of the arroyo running down to Mazuma, are the Kindergarten and Wihuja mines, both on the same vein. The Kindergarten mine, owned by the Seven Troughs Kindergarten Mining Co., is developed by an adit and by an inclined shaft 280 ft. deep on the dip. A new vertical shaft, being sunk at the time of visit in August, 1908, was expected to cut the vein at a depth of about 300 ft. The Wihuja is a lease on the ground of the Seven Troughs Therien Gold Mining Co., and is opened by an inclined shaft to a vertical depth of about 212 ft. The Kindergarten and Wihuja workings are connected. Other leases on Therien ground, in operation but not productive in 1908, were the Bard and Jess (175 ft. deep), the Tyler, and the Sandifer leases. On the north side of the canyon, close to town, are the Mazuma Hills and Reagan mines, both productive. The Mazuma Hills mine is owned and operated by the Mazuma Hills Mining Co.; the Reagan is a lease on a vein lying east of the Mazuma Hills vein, but within the ground of that company. The Mazuma Hills mine is opened by a main adit 700 ft. long. Winzes from this adit connect with a level 100 ft. below and about 500 ft. long. There is also an upper disused adit about 100 ft. above the main level. The Reagan is worked through a shaft that was 165 ft. deep at the time of visit. Only the 65-ft. level, however, could then be examined, the bottom level being temporarily under water, pending the installation of pumps. South of the Mazuma Hills and Reagan mines is the Sandifer lease on Therien ground. Here, in the bottom of the canyon, a shaft is being sunk in expectation of finding ore in the southern parts of the Mazuma Hills and Reagan veins. North of the Reagan shaft, on the same fissure zone, are the Chadbourne and Bradley leases, whose shafts are respectively 135 and 165 ft. deep. Neither had been productive up to August, 1908. On the hillside a short distance above the mouth of the Mazuma Hills adit is the shaft of the Hayes-Mazuma lease. This was being sunk through rhyolite at the time of visit and was not in ore. Between the workings mentioned and the head of the ravine north of Seven Troughs are the Eclipse shaft, Providence adit, and various smaller unproductive openings made by lessees and prospectors. On the north side of Seven Troughs canyon, about a quarter of a mile below the town, is the adit of the Seven Troughs Tomboy Mining Co. This is a cross-cut running $N. 50^{\circ} E.$ At the time of visit it was 800 ft. long, and the intention of the company was to carry it 400 ft. farther. The adit first penetrates about 150 ft. of rhyolite and then goes through a seam of gouge into soft pyritized tuffaceous beds with a general low dip to the northeast. These are cut by many faults, probably of small throw, and contain some masses of basalt. About 350 ft. from the portal the adit goes through another seam of gouge into rhyolitic (or possibly andesitic) breccia cut by dikes of glass or obsidian. Lower down the canyon, near Mazuma, considerable tunneling has been done on the Badger group of claims. These workings were not examined. In Wildhorse canyon prospecting was in

progress in 1908 on the Wild Bull, North Pole, and other claims. The Wild Bull showed a little ore, but no shipments had been made. North of this canyon the only active prospecting appeared to be on the Snow Squall claim in Victor canyon, south of Farrell. It was reported that lessees had found good ore in sinking their shaft, but the workings were not visited. From the saddle south of Seven Troughs a long ravine runs south and then turns southeast, embouching at Vernon. In the upper part of this ravine is the Dixie Queen shaft 230 ft. deep and the Cleghorn Consolidated and Signal adits, from 200 to 300 ft. in length. Some lessees also were operating in 1908 on property of the Signal Peak Mining Co., high up on the ridge south of Seven Troughs, but owing to lack of time their shaft was not visited. About halfway down the canyon and about two miles south of Seven Troughs is the Fairview mine reported at the time of visit to be 650 ft. deep. This mine is known to have had some bunches of very rich ore in the upper levels and is said to have shipped about \$65,000. No stoping was in progress at the time of visit and the shaft was being sunk through hard basalt. The mine is owned by practically the same people that control the Kindergarten and Therien properties at Seven Troughs. In contrast to the attitude of other mine-owners in the district they showed disinclination to impart information and refused access to the Fairview mine. Adjoining the Fairview workings on the north is the Harris lease, on Fairview ground, with a shaft 185 ft. deep. The dump is basalt, much of it being vesicular. There were two mills in operation in the latter part of 1908, one belonging to the Kindergarten company and situated at Seven Troughs, the other belonging to the Mazuma Hills company and situated at Mazuma. Both are 10-stamp mills with amalgamating plates, Wilfleys, and vanners. No attempt is made to cyanide the tailing or save it.

Most of the dikes and fissures near Seven Troughs have a nearly north-south trend. The veins as a whole consist of soft crushed material and do not outcrop above the surface. They represent zones of brecciation or of small fissures, along which movement has continued since the spaces originally formed were filled with quartz. Consequently the typical quartz of the district is friable or sugary, and generally contains or is mingled with many fragments of shattered rock. Clear solid masses of quartz, even of small size, are rare. The veins on the whole are rather narrow, ranging from a few inches up to about two feet in width. It is possible, however, that the average working width may be considerably increased when the district has better facilities for handling and treating ore.

The valuable constituent of the lodes is native gold containing a considerable proportion of silver, and consequently of a rather pale color. In most of the rich ore the gold is visible either as clusters of small irregular particles or as coarse crystalline aggregates. No complete well formed crystals were seen, but there is a noticeable tendency of the coarser gold to form crystal facets. The Mazuma Hills, Reagan, and Fairview mines have afforded some very showy specimens of bright yellow gold interlamin-

ated with firm quartz or enveloping fragments of altered country rock. Loose nugget-like masses up to an ounce in weight have been found in soft crushed vein matter in the Reagan lease. The rich bunches of gold are not uniformly distributed through the veins, and it is difficult in some cases to secure clean sorting. It was found, for example, that material thrown over the Reagan dump as waste or as low-grade ore to be treated later carried small quartz stringers, and that some of these, when broken across, contained coarse native gold.

The tenor of the ores, as is to be expected, has a wide range. A mill run from the Reagan lease in August, 1908, averaged about \$130 per ton. Picked ore from the Fairview, Mazuma Hills, and Reagan mines has yielded at the rate of several thousand dollars per ton. In the Kindergarten mine the ratio of gold to silver by weight is said to vary from 1:2 to 1:3 near the surface, but at the bottom of the mine to be nearly 1:1. Assay certificates of rich ore from the Reagan lease, seen in Seven Troughs, showed a ratio of nearly 2 of gold to 1 of silver. At one place on the lower level of the Mazuma Hills mine quartz carrying a little chalcopyrite is reported to have yielded on assay 200 oz. of silver and 0.3 oz. of gold per ton.

The three important veins near Seven Troughs are the Mazuma Hills, Reagan, and Kindergarten veins. The first two, known only on the north side of the canyon, strike about N. 10° E. and dip from 60 to 65° W. The Reagan vein lies about 40 ft. east of the Mazuma Hills vein. The Kindergarten vein, on the south side of the canyon, strikes N. 63° E. and dips south. The dip varies from 60° near the surface to 22° on some parts of the 40-ft. level. The dip at the bottom level is about 35° (vertical depth 212 ft.). The stope length of the ore-shoot is about 130 ft., and the average workable width of ore is probably about 2. At the northeast end of the mine the vein appears to be cut off by a zone of north-south fissures in which no ore had been found at the time of visit.

The country rock varies from place to place in each mine. The Kindergarten and Wihuja workings, as seen in 1908, are mainly in basalt. Part of this is a soft altered amygdaloidal variety, evidently an extrusive rock. Other parts are a dense olivinitic variety that apparently cuts the amygdaloidal flow rock. Masses of soft light-colored rock, either rhyolite or mica andesite, but too decomposed as a rule for satisfactory determination, occur at unexpected places on both sides of the vein. They probably represent intrusions somewhat displaced by faulting.

The Mazuma Hills vein follows a basalt dike that varies in width from a fraction of an inch to more than 6 ft. The general country rock is a nearly white altered rock that the microscope shows to have been originally a highly glassy rhyolitic tuff or flow breccia. It is now devitrified into a fine-grained, obscurely crystalline aggregate and contains minute disseminated crystals of pyrite. The best ore is on the foot-wall or east side of the dike, and appears to be for the most part minutely fissured and silicified rhyolite tuff; but some ore extends into the basalt. At one place there is a second vein, about 10

ft. east of the main fissure zone and with a little lower dip. The horse of rhyolite tuff between the two is said to be all low-grade ore. Some of the best ore in the mine is reported to occur as small gold-bearing stringers traversing hard rhyolitic tuff.

The Reagan vein also follows a basaltic dike and shows considerable resemblance to the Mazuma Hills vein. The general country rock, however, is more varied. Much of it is a highly altered volcanic glass, apparently basaltic, which, owing to its originally brittle character, has been elaborately and minutely cracked and fissured. Many of the cracks are microscopic and have a perlitic arrangement. This rock is generally greenish gray, and much of it is so fine-grained that its mineralogical character can not be ascertained under the microscope. Other varieties show a few microscopic phenocrysts of plagioclase, partly altered to calcite, and a groundmass in which traces of an original microlitic texture can be detected. Much of the rich ore of the Reagan lease consists of this altered basaltic glass, in which the irregular cracks have been filled with quartz carrying free gold. The secondary minerals identified in the glass itself are pyrite, quartz, calcite, and apparently a little chlorite. Calcite is not abundant, which is rather surprising in view of the calcic composition of basalt. In some places altered glass of the kind described passes into a highly amygdaloidal variety that is well exposed in an adit on the Sandifer lease just south of the Reagan mine and in the Bradley lease to the north. In the Sandifer lease the vesicles are only partly filled by clear projecting crystals of quartz. In the Bradley lease some are filled with quartz and some with calcite. Pyrite is disseminated through the light greenish gray altered substance of both varieties, and a few vesicles were noted that were first lined with pyrite and then filled with quartz. Although pyrite is fairly abundant throughout the altered basaltic and tuffaceous rocks near the ores, and occurs with quartz in very small, almost microscopic veinlets, it appears to be rare in the generally larger veinlets in which are the visible particles of gold. These veinlets, so far as could be seen in 1908, contain little or no pyrite. According to D. H. Skea, some proustite and possibly some stephanite or polybasite were found with the gold in the Fairview mine, and a little chalcopyrite and specks of a gray mineral resembling bornite were noted in 1908 on the bottom level of the Mazuma Hills mine in quartz similar to that elsewhere rich in gold; but as a rule the auriferous quartz is notably free from any other mineral than gold. Stibnite occurs in friable lenticular masses of considerable size in soft crushed basalt in the Chadbourne lease, and is said to have been found also in the Reagan lease. It does not, however, appear to have any intimate connection with rich ore. A little native silver is said to have been panned from the ore of the Wild Bull mine in Wildhorse canyon.

All of the ore visible in 1908 was within the range of oxidation. The results of weathering, however, owing to the very small quantity of pyrite in the veinlets, are not conspicuous, and there appears to be no very definite change from oxidized to sulphide ores. Pyrite and stibnite, as has been seen, both oc-

cur in connection with the ore deposits above the ground-water level. The surface of the underground water near Seven Troughs corresponds approximately to the bottom of the canyon, in which is some running water, and doubtless rises a little higher in the adjacent ridges. In August, 1908, water was just making its appearance in the bottom of the Kindergarten mine at a depth of 212 ft., and the lessees of the Reagan, 165 ft. deep, were putting in a pump in order to work their lower level.

Not enough mining or geologic work has been done to enable anyone to pass final judgment on the future of the Seven Troughs district. The presence of very rich, easily treated gold-silver ore in fair abundance at several places within an area some six miles in length is highly encouraging. On the other hand, it should be noted that the veins are not of great size and apparently are not as a rule of great length or persistence, and their character at any considerable depth below possible superficial enrichment is yet undetermined. Moreover, it is evident that in most of the mines the country rock may be expected to differ at various depths, and it is yet to be proved that the rocks beneath the tuffs and basalt in which most of the known ore occurs will be equally productive. In short, while the district is a most promising one for prospecting and developing, it is yet too early to regard it as one certain to yield largely for a period of many years.

The Prospector.

This department makes a charge of 25 cents to subscribers not in arrears and \$3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

F. P. S., Robinson, Utah: Altered dioritic rock.

W. H. S., Lundy, California: Limonite with quartz.

R. J. H., Agua Salada, Mexico: No. 1 and 2 are altered gabbroitic rock.

D. A. H., Telluride, Colorado: The black specimen is obsidian and the white rock is quartz porphyry.

E. S., Michoacan, Mexico: No. 1, basalt; No. 2, andesite; No. 3, andesite; No. 4, andesite; No. 5, porphyrite; No. 6, metamorphosed volcanic; No. 7, jasper.

E. C. M., Mazuma, Nevada: No. 1, clay with pyrite crystals; No. 2, chloritic mass with pyrite; No. 3, chlorite and calcite; No. 4, silicious limestone with pyrite.

Zinc ferrocyanide, according to Rupp, may be determined as follows: the Zn solution is made as neutral as possible and Rochelle salt added. It is then mixed with a known volume of ferrocyanide solution, diluted to 50 or 100 c.c., and allowed to stand about $\frac{1}{2}$ hr. for the formation of the denser $K_2Zn_3(FeCy_6)_2$. Then an excess of N/10 I solution (measured) is stirred in, and the mixture allowed to stand for 1 hr., when it is titrated with $Na_2S_2O_3$. Ferriecyanide results from the action of the I on the K_2FeCy_6 . 1 c.c. N/10 I = 0.00981 Zn.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Theory of Volcanic Action and Ore Deposition.

The Editor:

Sir—In a recent paper read before the members of the Institution of Mining & Metallurgy, in London, Hiram W. Hixon advances a new and interesting theory of volcanic action and ore deposition. The basis of this theory is that the earth was at one time an incandescent sun, with a temperature above the critical temperature of all the matter composing it. Dalton showed that gases of different densities, if allowed to mix, would form, in time, a uniform gaseous mixture. Hence it follows that each gas entering into the composition of such a sun would diffuse throughout the whole planet, even though its density at the centre were greater than the density of the corresponding solid. Considering for the moment that the present condition of the earth is derived from the gaseous state mentioned, Mr. Hixon maintains that it differs therefrom only through the pressure of a crust imprisoning the gases and exerting great pressure upon them.

It is said that a rigidity equal to that of a sphere of steel would be required to resist the tidal action. The question immediately arises as to the limit of rigidity to which gases under pressure may attain. Rigidity is a property of solids acquired by the reduction of the amplitude of vibration of their molecules with relation to each other. If by pressure upon a gas, existing at a temperature above its critical temperature, the amplitude of its molecular vibrations be made less than in the corresponding solid, its density must be greater.

It is known that there is an increase in temperature of approximately 1°C. for each 100 ft. of depth. This places the zone of critical temperature about one hundred miles below the surface, and it means that all matter from the limits of this zone to the centre of the earth is in a gaseous state. Through secular cooling the outer surface of this zone is reduced below the critical temperature of a part of some of the elemental or combined gases diffused through it. Since pressure will raise the melting point of a solid, enough pressure will raise it to the critical temperature; and the solid will pass directly to the gaseous state, or vice versa, without becoming a liquid. The gases will pass, then, to the solid state, and expand in so doing, it being assumed that the pressure has given the gas a greater density than the corresponding solid. Thus would result an addition of matter of high critical temperature to the flowage zone of the solid crust. The gases of low critical temperature would saturate the flowage zone and segregate at its outer rim, or just beneath the zone of fracture. Here they would accumulate until super-saturation of the periphery of the flowage zone resulted and sufficient elastic force to rupture the zone of fracture had accrued. In escaping through

the zone of fracture, these gases of low critical temperature give rise to the phenomena of volcanic action, earthquakes, elevations, intrusion of dikes and laccoliths, faulting and folding, accumulation of hydro-carbons, and ore deposition. The above theory leads to some interesting deductions, and explains much that has hitherto caused wide differences in opinion.

THORINGTON CHASE.

Concepción del Oro, Mexico, November 21.

The Qualified Mining Engineer.

The Editor:

Sir—Some hold that only the man who has had a university training and can write E. M. after his name has a right to the title of mining engineer. I would suggest that the only degree which a university should grant to a young fellow after three or four years study, should be that of Q. S. M. or Qualified Student of Mining, or possibly A. E. M., Associate Engineer of Mines; never E. M. In my opinion a mining engineer is a man qualified to solve the problems of mining, without regard to how, when, or where he acquired the knowledge. A university student is no more qualified than a junior lieutenant is to be general. An engineering course at a university does not by any means guarantee that a young fellow will ever become a mining engineer. It only gives him a good start. In practical life mining might even be distasteful to him. An engineer, especially a mining engineer, is first born, then discovers that he has the instinct, and is finally molded by circumstances, and proved by his results. I believe that the older men of the profession will endorse this; but what the public and the investor want to know is how to judge an engineer and whom to trust. The routine of another branch of the profession, marine engineering, might be copied.

In the mine the safety of the lives of hundreds of men, and the security of vast investments is just as dependent upon the engineer as in the case of a ship at sea. Why then should not the title of Mining Engineer be given only after examination? Mining is the life of every new country, and everything that can be done to stimulate the industry and to train the rising generation to higher efficiency is of economic value to the nation. To insure that the men directing mines are properly qualified would be the first and most certain method of increasing the wealth resulting from mining and of giving guarantee to the investor. The best means of doing this and of solving the question, who is a Mining Engineer, would be to bring the various universities and schools of mines and the Geological Survey into relationship with a strong Federal Department of Mines. A competent board of examiners should be appointed with powers to confer progressive degrees, titles, and licenses; the routine being more or less as follows: Any person who desires to enter the profession should register as an S. M., that is a Student of Mining. If he enters any school of mines or university and goes through the regular course he might receive the degree of A. E. M., Associate Engineer of Mines, subject to examination. If the individual is actually employed at mining or other work, and is gaining

his theoretical knowledge by self-instruction, he might come before the examiners, and on passing a simple examination covering the elements of mining engineering he should be given the title of Q. S. M., Qualified Student of Mining. Then if after working underground in various capacities and proving one year's practical experience, he should be eligible for the examination for mine foreman, and on passing that for third or second-class certificate. First-class certificates would only be granted to old and experienced hands. The same routine might apply also to the title of mill superintendent, underground surveyor, mine mechanic, assayer, and metallurgist. Six months practical experience should be required in each case.

As soon as a mining man could show certificates of all of the above qualifications, with the exception that he need not present both a mill superintendent's certificate and a smelter superintendent's certificate, he should be eligible for examination as 'mine superintendent', and by passing could obtain a third-class certificate if he had three years' practical experience. Second, first, and chief's certificates should be granted only after two years' further experience in each grade, and subject to more rigorous examinations.

Certificates should also be given on examination, and with proof of at least six months' practical experience, in each of the following: field geology and mineralogy; economic geology; topographic surveying; the elements of road building and tramway construction; hydraulic engineering, including some knowledge of hydro-electric power-plant work. This would give a total of at least two years field work. With a third-class superintendent's certificate, which with the above field-work certificates would give a total of five years' practical experience, a man should be eligible for the examination of Engineer of Mines and could obtain either a fourth, third, or second-class certificate, according to his proof of capacity at the examinations. A first-class or Chief Engineer's certificate should only be granted after at least two years further experience as manager of some mine and another examination.

The above, of course, only outlines a rough scheme. I do not propose competitive examinations, nor anything complex or difficult; only sufficient to show general proficiency and reliability. Neither would I propose that this be made compulsory, except in the case of men employed at large mines, and especially at coal mines. I think that many examinations having reference to minor posts, and specialists' branches of work, might be held, and certificates granted. Licenses should be compulsory wherever men are controlling work in which human life is in danger, such as coal miners, smelter-bosses, hoisting-engineers, foremen, timbermen, and men in charge of explosives and ventilation.

If such a system were to be established, for the first two years the examinations might be made simple, and facilities granted to engineers already actively engaged in the profession to easily obtain their certificates. The examinations should be open to all classes and to all nationalities. After a few years, as the system developed and experience was

gained, the examinations could be made more severe, and the practical experience required more thorough.

In addition to this the Department of Mines should issue an official monthly bulletin, in which the mining statistics, and the results of official investigations, tests, and experiments would be published, giving data that would be of practical assistance to mining men. Surely mining deserves some such recognition as is given to Agriculture and Forestry.

JOHN M. NICOL.

Mexico, November 22.

Modern Quicksilver Reduction.

The Editor:

Sir—In your issue of November 20, H. W. Turner questions the correctness of Mr. Strauss' statement as to the amount of quicksilver recovered from soot. In reply I beg to state that formerly when handling ore over 1% in value at New Almaden, more quicksilver was obtained direct from the condensers, but at present the saving is dependent on a number of conditions: (1) The character of the ore. (2) The grade of the ore. (3) The kind of fuel, whether wood or oil, and in regard to the latter whether steam or air is used in injecting the oil.

When treating a clayey ore, such as we have at New Almaden, a certain amount of fine material is carried over to the condensers, and when this comes in contact with the steam (as we use fuel oil injected by steam), it forms a sticky muddy soot, which tends to hold the quicksilver mechanically as long as it is wet, and as long as it stays in the condensers it stays wet. When a high-grade ore of 1% or over is treated, the percentage of mercurial vapor in proportion to other gases is greater and the tendency is to condense closer to the furnaces than where a lower grade ore of, say, 0.2 to 0.3%, such as is now being treated.

In the first case mentioned the soot becomes surcharged with mercury and some of it runs out of the condensers, nearest to the furnace, while in the second case it is carried farther back from the furnace, and in consequence the soot in the condensers close to the furnace is lower in grade and little, if any, runs out of the soot and practically all is recovered from the soot. In our case per 100 flasks produced we seldom get over three or four out of the condensers on ore of 0.2 to 0.3% grade. (3) With wood a dryer soot is found (even though a larger quantity), and consequently more quicksilver tends to run out of the soot than with oil injected by steam. What the result would be if the oil were injected by compressed air I am not in position to state, but would like to hear from other correspondents.

ARTHUR FEUST.

New Almaden, California, November 22.

[Mr. Turner's note in regard to the relative amount of mercury obtained from soot, was intended to call attention to the usual results and not to any special case. In 1882, the total production of quicksilver at New Almaden was 28,070 flasks, of which only 1122 were obtained from soot, or only 4 per cent, according to S. B. Christy.*—EDITOR.]

*Trans. Am. Inst. Min Eng., Vol. XIII, p. 582.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A lease granting the right to extract ore from a certain named level of a mine includes the right of extraction to the next level above.

The recent mining act of California does not affect nor abolish any mining district or the rules and regulations thereof.

The number of locations within a group upon or outside of which the annual expenditure may be made is immaterial except in the case of petroleum oil placer claims. In the latter case the locations within such group must not exceed five.

Gas producers consist essentially of vertical cylinders of from 8 to 12 ft. diam. and 10 to 15 ft. high lined with fire-brick. At the bottom is a grate on which is supported a mass of fuel 6 to 7 ft. deep. From the top of the producer a duct leads to the main gas-flue and at the base are openings for the admission of steam and air under blast.

'Cost book' is a term employed in the tin mines of Devon and Cornwall, recognized also by the so-called Stannaries Act, that includes all books and papers relating to the mine which for the time being are kept by the 'purser', or, in the absence of such an official, by the secretary. The last Stannaries Act, passed by the Parliament in 1869, was repealed by the Statute Law Revision Act of 1893.

Fuel value is stated in English and American engineering literature in terms of b. t. u. (British thermal units). The simplest formula for calculation is the modified Mahler, which is

$$20050 C + 67500 H - 5400 = \text{b. t. u.}$$

In this formula C=the carbon present by weight, and H=the hydrogen; both expressed decimally as to the total weight of the fuel.

Strength of pine increases rapidly with the number of rings of annual growth per inch, reaching a maximum between 8 and 10 rings, and then falling off slightly as a rule. Strength also increases with the weight of the timber, the greatest weight being found in moderately old trees. The strength of sap-wood depends upon the period of growth when it was formed. In large-sized trees the sap-wood is weak; on the other hand, in comparatively young trees the sap-wood is heavy and strong.

Pitch-blende may be detected by the following properties: Color, pitch black, velvety black, brownish sometimes with a grayish or greenish cast. The streak on rough porcelain, that is, the edge of a broken plate, is brownish black, olive green, or grayish. Lustre, dull, metallic, greasy, pitchlike. Fracture, conchoidal, that is, with smooth curved surfaces, to uneven; brittle. Hardness, less than quartz. It is not scratched by a knifeblade unless weathered. Specific gravity, heavier than iron or steel; also heavier than galena.

The Welsh process consists in treating copper ore, sulphide and oxide as well as silicious, by a series of roastings and fusions to raise the grade finally to blister. This is subsequently refined. The process possesses the advantage that a variety of ores, both coarse and fine, may be treated in a few reverberatory furnaces without large investment in plant. For a small tonnage, it is possible to produce metallic copper on the spot. The process includes five operations: (1) calcining the ore; (2) fusion; (3) calcining coarse metal; (4) second reverberatory fusion; (5) 'roasting' and formation of blister copper.

Tungsten is of wide occurrence, but the individual deposits can hardly be said to be large. As a rule they are 'pockety'—that is, they occur in lenticular masses or small shoots. Many of those at the surface are quickly and easily mined, but it may then take all the profits derived from the first orebody to find another one. The tungsten minerals used as ores are hübnerite, a tungstate of manganese; wulframite, a tungstate of manganese and iron; ferberite, a tungstate of iron; and scheelite, a tungstate of calcium. They generally occur in veins cutting igneous rocks that contain much silica, such as granite and granodiorite.

Losses in electrical generators may be determined as a speed function by using what is known as a deceleration curve. With the water shut off from the turbine the machine is brought up to speed by interconnecting the generators on two wheels, one of which can take water, bringing them up to more than their running speed, and then cutting loose that wheel in which the electrical generator losses are to be determined. Knowing the moment of inertia of the rotating parts, which can be readily calculated, observing the negative time-differential of the speed, and multiplying by the moment of inertia, the power-losses can be readily plotted as a time-function. Another way is by an electrical braking device; the simple connection of the electrical generator through a known resistance and measuring the current carried by it will show what the power usefully generated does in the braking of the machine.

Churn-drills are applicable to prospecting only of comparatively shallow deposits of large volume. They have an advantage over the diamond-drill in exposing a larger cross-section and in applicability to loose material. The doubt which usually obtains as to the exact horizon from which the sample comes, and the finely ground state of the material makes them of small value in testing narrow high-grade veins. They have proved widely useful in prospecting alluvial deposits and the porphyry coppers and in drilling through barren cover preparatory to testing iron ore horizons with the more expensive diamond-drill. Churn-drills are used altogether in exploration in the Joplin and Wisconsin zinc regions where the ground is much fractured and flinty. In the disseminated lead region of southeastern Missouri the diamond-drill is preferred. The firmer ground, and greater freedom from flint makes its use possible.

Special Correspondence.

WASHINGTON.

Coal Mine Accidents. — Oil Land Withdrawals. — Proposed Leasing System.

As a part of the campaign of the United States Geological Survey to reduce the number of fatalities in coal mines, officers of the Technologic Branch have been addressing the miners of Pennsylvania and Tennessee. J. A. Holmes has just completed a series of talks to the miners of the anthracite region on the use of explosives, detailing the results of the tests at the Pittsburg experiment station. Col. Dunn, U. S. A. chief of the Bureau for the Safe Transportation of Explosives, and C. E. Munroe, of George Washington University, also addressed the miners. H. M. Wilson, chief engineer, Technologic branch; J. C. Roberts, assistant chief engineer, and A. C. Ramsey, mining engineer, addressed the miners and operators in Tennessee. The German Government recently sent a commission into Belgium to study the methods employed in the coal mines of that country in combatting explosions caused by fire-damp. Such explosions were apparently for a long time unknown in German mines, but now on account of the increasing depths of the mines operated the dangers are beginning to be more keenly realized.

In connection with the recent withdrawal from entry of

Rescue Corps at Government Testing Station, Pittsburg.

over 3,000,000 acres of public petroleum lands in California, Wyoming, Utah, and Oregon, the following statement is given out by C. W. Hayes, chief geologist of the United States Geological Survey. "To remedy the present unsatisfactory conditions by which public oil lands have to be entered under a law framed primarily to provide for placer gold mining entries, it is generally admitted that a radical revision of the American mining law is necessary. Anticipating that Congress will recognize and meet this need, the Secretary of the Interior has withdrawn from all forms of entry all vacant public lands designated by the Geological Survey as probably containing oil and gas. This Executive action is, however, only temporary and is intended to preserve the *status quo* until Congress acts. When the present placer mining law was enacted, probably no one had any idea that it would ever be made to cover mineral deposits so far removed in every essential characteristic from gold-bearing gravels as are oil and gas. When oil was found on the public lands no other law was on the statute books under which title to it could be acquired, and this anomalous and wholly unsatisfactory condition still holds, to the great detriment both of the Government and of the oil industry. The fundamental basis of a location under the placer law is discovery, and the courts have held uniformly that there can be no legal location until there has been a discovery. But in the

nature of the case there can be no discovery of oil until a well has been drilled at great expense. Since ordinarily there are no surface indications of the oil, the well must be drilled upon purely geological inference. It follows, therefore, that the driller is wholly unprotected against rival claimants to the land until he has completed his first well, or he is forced to make a false claim to discovery on which to base his location. One common method of evading the law is to locate oil under the guise of a gypsum claim. In many of the California oilfields the surface soil contains a small amount of gypsum, although rarely in sufficient quantity or purity to be profitably mined, even if favorably located for transportation and market. It affords a pretext, however, for a location under the placer law, and large numbers of claims have been patented where it is a matter of common knowledge that the real object is to acquire title to the oil. In this way land worth thousands of dollars per acre has been acquired from the Government for \$2.50 per acre, and this without oil development. Moreover, it is not generally the man of small means, but rather the wealthy corporation that resorts to this subterfuge to secure title. Although many of the oilfields in the public land States, and particularly those in California, are in regions wholly devoid of agricultural possibilities, no sooner is a successful well drilled than the entire district is covered by homestead and scrip entries, the purpose of which is to secure title to the oil under cover of the agricultural land laws. It is to meet these conditions that a thorough revision of the law is needed.

"Any law which will adequately meet the requirements of the case must recognize the fundamental difference between oil and gas and other minerals, namely, mobility. These elusive products can be drawn from a distance underground across boundary lines, and exclusive title to the product is acquired only after it reaches the surface. It follows, therefore, that oil can be disposed of by the Government or other owner of the land in which it occurs only as a commodity, and not in terms of acres like coal or other minerals occupying fixed locations. This difference is so well recognized that it has determined the leasing system which is practically universal in all the oilfields where the land is in private ownership. The Government cannot do better than to adopt the plan which has been worked out through long experience, and, where the holdings are sufficiently large, has been found thoroughly satisfactory, both to the oil operator and to the private land owner. Why should not the Government as a land owner deal directly with the producer rather than through the intervention of a middleman to whom title to the land has passed? Any ideal or practical law must further recognize the fact that actual discovery involves heavy expenditure and considerable time, and that the prospector must be adequately protected in his investment before as well as after the discovery is made. The area to which he is given a preferred right must therefore be sufficiently large to justify his initial heavy investment and in such compact shape as to protect his discovery from encroachment by drilling on subsequent entries. A well considered leasing law will give certain incidental advantages of great importance both to the Government and to the oil operator. It will constitute the most effective means for the conservation of the oil and gas resources of the country by enabling the Government to regulate developments so as to prevent much of the criminal waste now prevalent.

"Under the present system the owner of a 20-acre placer claim is compelled to drill and pump the oil from his land with all possible speed, regardless of transportation facilities or market, for otherwise his competitors on adjoining claims will take a large share of it away from him. In the resulting feverish exploitation half a dozen or more wells may be drilled when one would have secured the same amount of oil, a serious economic waste to the Nation and a heavy tax on the ultimate consumer. Also, unrestricted drilling by careless or ignorant operators may ruin a valuable field by admitting water to the oil-sand from a higher or lower water-bearing stratum. Many examples of criminal waste resulting from the unrestricted exploitation of oilfields might be cited. The Government is not only the largest owner of oil lands, but it is likely to be the largest con-

sumer. The six largest battleships in commission or under construction in the American Navy are equipped for the use of either oil or coal, and the fourteen largest destroyers use oil exclusively. The question of fuel supply for these vessels is certain to become an exceedingly important one in the near future, and the law should provide a means of perpetuating a supply for this certain future need. The fact is gaining recognition that the natural resources remaining in the possession of the Government are the heritage of the whole people, and the idea that they should be economically utilized for the general good rather than exploited for the enrichment of a few individuals is rapidly crystallizing into public opinion. The enactment by Congress of a law providing for the leasing of oil lands will be a logical and much needed action in the Government's management of its great petroleum property."

Bituminous coal operators representing that industry in Ohio, Pennsylvania, Kentucky, Indiana, Illinois, and West Virginia, called upon the President, November 24, and requested that the railroads of the United States be permitted to pool freight under supervision of the Government. They declare that at the present time and for some time past operators of the different districts have been furnished with only 40 to 48% of the cars needed to move their coal and that they are losing millions of dollars through the delays. This, they said, could be avoided were other roads having idle cars permitted to come in and help move the coal. Mr. Taft was urged to make plain in his coming message the necessity of taking immediate action against the car shortages and freight congestions. The members of the committee who met the President were Samuel A. Taylor, representing the Pittsburgh District Coal Operators; T. K. Maher, of the Pittsburgh Vein Coal Operators Association, of Eastern Ohio; and Howard Mannington, of Columbus, Ohio, representing the Ohio Coal Operators' Association. Tom L. Lewis, president of the United Mine Workers, was also present at the conference. The President promised to give considerable thought to the request of the coal men. W. H. Thompson, editor of the *Daily News Miner*, Fairbanks, Alaska, is in Washington waiting for Congress to begin, when he will present a proposition for Alaska to have a more representative government. Mr. Thompson says Alaska is growing so rapidly that a Territorial governor and four Federal judges are not sufficient to take care of his country. He thinks Alaska is big enough for a territorial legislature.

LONDON.

Consolidated Gold Fields.—Simmer & Jack.—French Rand.

The Consolidated Gold Fields of South Africa depends nowadays for its profits almost entirely on the yield of gold by its subsidiaries rather than on the sale of properties. For many years Simmer & Jack was its chief producer, and within the last two or three years the output of other subsidiaries, namely Robinson Deep, Simmer East, and Knights Deep, has become important. The financing of new propositions in other countries is now more profitable. Rhodesia, West Africa, Russia, the United States, and South America receive attention from this company. To give some idea of the extent of the Gold Fields' operations on the Rand, I may mention that the subsidiary companies Simmer & Jack, Robinson Deep, Knights Deep, Simmer East, Jupiter, Simmer Deep, and Nigel Deep employ 1350 stamps and during the year ended August 31 produced 984,302 oz. of gold. The total stamps in operation on the Rand are 9842 and the yearly production 7,360,915 oz. The Gold Fields group employed 24 tube-mills out of the 144 on the Rand. The tons of ore crushed were 3,224,168 out of 22,033,857, and the stamp duty was 7.38 tons, as compared with 6.7 tons, the average over the Rand. The total mining profits of the group were £1,658,966 for the year ended August 31. During the year ended June 30 the profit made by the Gold Fields was £1,283,891, and dividends aggregating 35%, representing £700,000 were paid on the ordinary shares, as well as 6% on 1,250,000 preference shares of 5½% and £300,000 of debentures. Out of the year's profit £500,000 has been written off for depreciation of the mines, which are recognized as wasting assets. The Rhodesian interests of the

company include the Giant and Enterprice gold mines. Production at the first is still low, owing to the collapse of the main shaft. At the second the New Found Out property is giving fairly promising results. The discoveries at Abercorn in Rhodesia have induced the Consolidated Exploration & Development of Rhodesia, one of the subsidiary companies, to reorganize to the amount of £50,000. New capital has been provided and the Shamva claims are being acquired. Ancient workings have been traced along this property for 1500 ft. and the prospectors proved the veins by a series of shallow shafts and cross-cuts. Since the Gold Fields took up the property additional development has opened a body of banket 90 ft. wide assaying 12½ dwt. and at another point 30 ft. wide assaying 20 dwt. The labor question is causing the Gold Fields, as well as the other South African houses, some anxiety. Notwithstanding the increased number of natives employed and their greater efficiency due to the longer contracts made, there is still a shortage of labor owing to the great expansion of the gold industry.

The Simmer & Jack, the largest of the Gold Fields group, is one of the great mines of the Rand. According to the report for the year ended June 30, the ore raised amounted to 955,035 tons, of which 827,500 tons was sent to the mill. The 320-stamp mill crushed 831,040 tons and produced 145,613 oz. The six tube-mills treated 468,450 tons and yielded 60,969 oz. The sand plant treated 560,326 tons by cyanide and produced 66,521 oz., and the slime plant 270,514 tons producing 19,606. The total production was therefore 292,710 oz., valued at £1,233,151, the yield being 7.04 dwt. or £1 9s. 8d. per ton. The working expenses were £540,537, or 13s. per ton, leaving a profit of £694,186 or 16s. 8½d. per ton. The dividends distributed out of the year's profits totalled £675,000. Of the total ore won, 72% was broken by hand and 28 was mined by machines. The average stamp-duty was 7.43 tons per day. The average number of natives employed was 3658, or 500 less than during the previous year. This decrease is due to greater efficiency, gained by having yearly contracts. It is noteworthy also that only one shift per day is worked at this mine, resulting in a larger tonnage being won with less labor, a reduction in working costs, and increase in the profit. The amount of payable ore developed during the year was 895,732 tons. Owing to the reduction in costs it has been possible to include certain blocks of ore among the payable reserves. The reserves have been re-estimated on the new basis and are now given as 2,500,000 tons of an average assay value of 6½ dwt. During the year under review the assay value of the ore milled was 7.47 dwt., of which 7.04 dwt. was extracted, being a recovery of 94¼%. During the previous year the assay value was 8.14 dwt. with an almost identical rate of extraction. At the same time the cost fell from 16s. 2d. to 13s., and since the end of the financial year the cost has fallen to the extraordinarily low figure of 11s. 10d.

The troubles of the French Rand Gold Mine have suddenly come to an acute crisis, and the directors have decided on the temporary closing of the mine. The company belongs to the Wernher-Beit group and the property (in older days known as the Champ D'Or) is situated on the western end of the Rand at a point where the country is much broken. Probably it has been the most difficult to work of all the mines on the Rand for this reason. During the first half of the current year the mine suffered severely from floods, which disorganize mining and development, and for some months serious losses were sustained. On recovery from these troubles, the labor supply began to fail, the working force dropping from 1840 in April to 1178 in September. For the past 18 months the eastern part of the mine has been gradually abandoned and work concentrated at the western portion, where more encouraging results have lately been obtained. As much as 1032 ft. of development was done during September, and the results point to the existence of some unbroken stretches of reef of encouraging value. However, having regard to the limited ore reserves and shortness of labor, it has been found necessary to alter the policy of the company. It has been finally decided to close down until technical and financial conditions improve.

BRITISH COLUMBIA.**Coast District Mines. — Copper and Iron on Texada Island. — Lime Kilns.**

Mining of metalliferous minerals in the Coast district of British Columbia is not done on a large scale at the present time. In what is officially known as the New Westminster district work is practically restricted to two properties, the Britannia group, on Howe sound, and the Swayne group, on Lynn creek, eight or nine miles from the city of Vancouver. At the former about 100 men are employed, at the mines on Britannia mountain, and the mill and concentrating plant at Britannia Beach. In the mines exploration of the big orebodies is being continued by adits and shafts. At the mill experimental work in concentration is in progress. Meanwhile production is not on a large scale; only the hand-picked crude ore of higher grade and the concentrate made being shipped to the smelter. Zinc having been found in association with iron and chalcopryrite in a silicious gangue, a small Wetherill separating plant is being installed. At the Swayne group the Tyee Copper Co. is developing, but is not shipping to its smelting works at Ladysmith, Vancouver island, owing to the absence of transportation facilities.

On Texada island, also in the Coast district, the Marble

Mineral Resources of British Columbia.

Bay, Cornell, and Little Billy mines are being worked, and a cross-cut adit is being driven on a property known as the Malaspina mine. The Marble Bay, owned by the Tacoma Steel Co., is shipping to the smelter at Tacoma, Washington, from 1200 to 1500 tons of gold-copper ore per month. The first class ore averaging about \$30 per ton, and occasionally runs up to \$40, while the second grade returns about \$10. The ore is chiefly bornite, much of it contains \$10 per ton in gold, with silver up to \$5. The first class ore carries 5% or more of copper. The bornite ore occurs in considerable quantity, with indications of continuing down to a somewhat unusual depth. On the 960-ft. level the orebody has been developed for 210 ft. in length, with ore in the faces at both ends of the drift. It has a width of fully 20 ft. The Cornell, one of the Van Anda group, is being operated by the Northern Texada Mining Co., which also has a bond on the neighboring Copper Queen, of the same group. The Cornell is in the same mineral zone as the Marble Bay mine, and its ore is also bornite associated with chalcopryrite. Up to a few weeks ago shipments by the present operating company had totalled about 9000 tons, and the expectation was that the year's output would show an average of approximately 1000 tons per month, and the

quantity of copper recovered during the year would be about 1,250,000 lb. The Little Billy Mining Co., of Seattle, Washington, has about completed the installation of a new power plant, consisting of a 80 hp. Robb boiler with duplex feed-pump; a 5-drill Canadian Rand air-compressor; an air-receiver 8 ft. by 36 in., and a 7 by 10 double-cylinder, single-drum Jenckes hoist, all housed in a building 100 by 35 ft., and covered with corrugated galvanized iron. Other improvements in hand are the erection of a head-frame 35 ft. high over the shaft, putting in new ore-sorting tables, and building a trestle 500 ft. from sorting tables to shipping bunker on tidewater with a double track gravity tramway. The shaft, now 100 ft. in depth, is to be deepened to 200 ft. and a level opened to connect with the orebody, which has an average width of 8 ft. This orebody was located last year by J. T. Taylor, superintendent of the mine, and after the metal content of 220 tons of ore shipped to the smelter had been ascertained, the equipment of the property with a new power plant was undertaken. The Little Billy was the first property near Van Anda on which copper ore in quantity was found, but the attention of the then owning company having been diverted to the Copper Queen and later the Cornell, it was neglected. The Puget Sound Iron Co.'s big iron and copper property, on the west side of Texada island, long owned in San Francisco, is again attracting the attention of mining men. It is now under option to Duluth, Minnesota, men, the purchase price named being large. It consists of about 3000 acres of land having a frontage of nearly five miles on the Strait of Georgia. Its mineral resources are chiefly iron and copper ores in comparatively large quantity; especially the former. Magnetite occurs along a distance of fully two miles, showing conspicuously in several high bluffs in which quarries have been excavated, giving faces of solid iron ore. The three more prominent occurrences of iron are known as the Prescott, Paxton, and Lake deposits, respectively. From these, chiefly from the Prescott, about 30,000 tons of ore have been shipped, and practically all of this was smelted in a small furnace at Irondale, near Port Townsend, Washington. The grade of the magnetite is high, up to 68% iron. The pig iron it makes is of good quality. A provincial mining engineer estimates about 30,000,000 tons of ore in sight on the Prescott, which has been opened by an adit from just above high-water mark, and driven 700 ft. into the mountain, entering the orebody at 700 ft. below one of its outcrops on a big bluff. The adit cross-cuts the ore for 100 ft., but did not pass entirely through it. No attempt has yet been made to ascertain the depth of ore below this tunnel level, so the area covered by this deposit and the tonnage available are undetermined. The ore on the Prescott is a coarse-grained granular iron, while that on the Lake is fine-grained. The copper ore deposits occur generally in close association with the iron near its contact with the enclosing country rock. Altogether about 3000 tons of copper ore have been shipped. No work is now being done on the property, but in 1908 lessees spent something like \$40,000 on surface equipment and development. The former included the installation of a small steam power plant, construction of a horse-tramway about 6500 ft. to tidewater, the erection of ore-bunkers at both ends of the tramway, and a shipping dock about 400 ft. long in Iron cove. Had a fully competent mining engineer been in charge, the operation of the copper mine probably would have been continued, notwithstanding the tightness of the money market and low price of copper. Other resources of the big Iron mine property, by which designation it has been long known, are extensive beds of good clay, extending about two miles along the shore line and up to half a mile in width, fine forests, estimated to contain up to 150,000,000 ft. of merchantable timber, chiefly Douglas fir, with a much smaller proportion of cedar, and about 1000 acres of land suitable for cultivation. The property has been held for many years by men of large means who have not done much with it. It now seems improbable that these inactivities will continue. Besides the above mentioned properties there are on Texada island a number of mineral claims upon which more or less development has been done, but as a rule, re-

sults have not been profitable. A lime-burning industry is in a flourishing condition, the Tacoma Steel company, operating, under the same management as is in charge of its mine (Alexander Grant, of Van Anda), four lime kilns at Limekiln bay, near the northern end of the island. The combined capacity of these is 300 to 350 bbl. per day. The lime is of superior quality and finds a ready market in the British Columbia Coast cities, and those of Puget Sound. Formerly much of the product was shipped to Honolulu, Hawaii, but cheap water transportation to that place can not now be regularly obtained, so a nearer market had to be found. The industry, which was established about 12 years ago, gives regular employment to 22 men. The Queen Charlotte islands and Portland canal are also in what is known as the British Columbia Coast district, but notice of mining, which is becoming important, in these parts must be deferred.

TORONTO, CANADA.

Gillies Limit. — Cobalt Production and Development. — Elk Lake. — Gowganda. — Coal Merger. — Coal Reserves.

The latest sale of mining lands on the Gillies Limit in the Cobalt mining district on November 16 went off satisfactorily, considering the depression in the market. Thirty-seven out of 55 lots were disposed of by tender at a total

Map Showing Portion of Ontario.

amount of \$372,462, or an average price of \$482 per acre. The interest in the sale was stimulated by the good showing made by the Waldman, the Wyandoh, and other properties on the Limit, which are being energetically developed. On the Wyandoh a vein of smaltite 3 in. wide containing native silver was recently struck at a depth of 11 ft. in the shaft. Notwithstanding the big dividends recently announced by the Crown Reserve—or perhaps because of the big dividends—the stock unexpectedly took a considerable

drop without apparent reason other than the nervous condition of the public and the general want of confidence in the stability of Cobalts caused by the La Rose slump and the weakness of other much boomed issues. Reports as to actual conditions at the mine are decidedly favorable. Vein No. 18, the Ross, has been recently struck at the 200-ft. level, showing undiminished silver content and giving the mine another 100 ft. of high-grade ore. Cobalt Lake has made a good strike in the cross-cut 28 ft. north in the drift at the 190-ft. level and near the McKinley boundary. The vein is 30 in. wide and carries leaf silver. The Wettlaufer mine in South Lorrain is developing well. A block of ore weighing 400 lb. with a vein over 12 in. wide containing silver to the extent of 5000 oz. per ton, taken from the 140-ft. level, is on exhibition in Toronto. The Hargrave, which for over a year has been looking for the continuation of the rich No. 3 vein of the adjacent Kerr Lake Mining Co., cut it a few days ago at the 375-ft. level. A new vein recently discovered on the Rochester has been stripped for 125 ft. and found uniform. An assay gave 5231 oz. silver per ton. A shaft is being put down. On the Gifford a 200-ft. shaft has been put down with a 10-ft. sump and a station cut at 200 ft. A cross-cut run at this level has penetrated two good veins, one of them showing silver. At the North Cobalt mines a depth of 200 ft. has been reached, but the ore is of lower grade. The shaft will be put down 50 ft. farther. The mine made its first shipment two weeks ago. The Temiskaming stamp-mill of 30 stamps is completed, though some machinery has yet to be installed. The rock will be crushed down to $\frac{3}{4}$ in. before it leaves the rock-house at the shaft and will be conveyed by aerial tramway 487 ft. to the mill which stands on rising ground. The Otisse of Elk Lake has for some time been involved in litigation, S. Kenyon Stowé, an English capitalist, claiming \$400,000 damages for fraud and breach of contract on the part of the promoters in failing to carry out an agreement to sell their claims to him. Kenyon's suit has been dismissed on the ground that he was not ready to make the preliminary payment of \$10,000 on his option. The Reeve-Dobie mine, Gowganda, has 35 tons of high-grade ore ready for shipment and a large quantity of low-grade. The company has done four miles of trenching and has put down three shafts, the deepest being down 90 ft. Shipments from Cobalt are well maintained, those for the week ending November 13 amounting to 940 tons, and for the week ending November 20 to 584 tons. La Rose continued well in the lead.

The contemplated merger of the Dominion Iron & Steel Co. and the Dominion Coal Co., of Nova Scotia, is making decided headway after a period of tedious negotiations. The Steel company as a preliminary step has secured a controlling interest in the Coal company by taking over 50,000 shares of the holdings of James Ross, the president of the Coal company at \$95 per share. A condition of the transaction was that all other shareholders of the Coal company were to have an opportunity of disposing of their stock on the same terms, which a number have already done, giving the Steel company about two-thirds of the stock. The merger, therefore, may be said to be practically accomplished, though many details remain to be arranged, and it will be some time before the basis on which the final amalgamation of the companies is to be effected will be settled. Meanwhile the strike of the employees of the Coal company is practically over, so far as the company is concerned, and it is announced that no more men are required.

The Canadian Geological Survey has issued a comprehensive report by D. B. Dowling on the coalfields of Manitoba, Saskatchewan, Alberta, and eastern British Columbia, which, together with a historical review, a description of the geology and topography of the coal areas, and an account of the different classes of coals and their values, contains a concise statement of the known area and probable contents of the coalfields in the prairie section. The total is estimated at 143,490,000 tons classified as follows: anthracite, 400,000,000 tons; anthracite and semi-anthracite, 860,000,000; bituminous and some semi-anthracite, 43,070,000,000; coal (lower grade) and lignite coal, 21,000,000,000; and lignite, 78,160,000,000 tons.

NEW YORK.

Copper Situation. — J. Parke Channing on Visible Ore Supply. — Cole-Ryan and Miami. — Copper Merger Plans. — Bear Movement.

The copper surplus has been attacked from a new angle. J. Parke Channing, consulting engineer of the General Development Co., and vice-president of the Miami Copper Co., has stated to your correspondent that he thinks the copper producers are in much the same position as holders of timber lands have been in this country for the past 20 years. Mr. Channing states that he has been for some months making an exhaustive study of the copper ore reserves underground, covering ore in sight and possible future ores to be developed, arriving at as close an estimate as possible of the future production of the mines of the world, so far as can be done from present conditions. The conclusion at which Mr. Channing has arrived, is that the copper supplies of the world are as nearly exhausted as are the available timber supplies. This conclusion has been reached only after several months of close study of the copper statistics of the world and, voiced by so well known and competent an authority as Mr. Channing, is entitled to a great deal of weight. The parallel between copper and timber is a patent one. It has not been many years since it came as a shock and a surprise when we learned that the regions around the lakes of Michigan and Wisconsin were to furnish no more cheap white pine. We had heard talk of over-production, had seen the markets loaded with a surplus, consumption almost at a standstill, when with a little revival of building, white pine went into the list of luxuries. The country turned to southern lumber, and the pine forests of the South disappeared into the sawmill almost before their passing could be noted. There is timber, a great deal of it, left yet, but from the present time, timber will more nearly approach each year the price which will approximate the cost of reproduction. That is to say it will sell for what it costs to grow it. Unfortunately for the user of copper, the parallel stops short of this point. Reforestation can give lumber but no alchemy can replace ore reserves once extracted. Mr. Channing is inclined to consider the present copper surplus as a result of mere temporary market conditions, taking the stand that when the real upward swing of the metal market makes itself felt it will disappear more quickly than now seems possible, and that future demands, with the constantly growing uses of copper, will soon place the producer in a position to dictate the price of the metal within any limit which will not absolutely forbid consumption.

If Mr. Channing is correct in his position a constantly advancing price for copper through a period of years is economically inevitable, and would be one of the major inducements for the formation of the much discussed copper merger. That exhaustion of ore reserves should be found to be practically in sight, just when the metal market has been talking of over-production would be the natural course of events; how well this position is taken can only be determined by the future, but the question is vital and worthy of careful study. It may be definitely stated that negotiations are under way whereby the Cole-Ryan people are to secure a large interest, if not the control of the Miami Copper company. Diplomatic denials of such a deal have been made by all parties in interest, but, while details are lacking, there is no doubt as to the fact. Copper-merger news has been definitely lacking during the past week; the Standard Oil decision changed the atmosphere completely. For the present, at least, all plans seem to have been held up. A sudden deference to anti-corporation sentiment seems to have appeared; the smelter trust, the mention of which causes so many smaller mining operators to 'see red', has been definitely dropped from the organization plans. The whole scheme of the combination appears to have been shifted from a pattern following the idea of the Standard Oil company, in owning a sufficient production to control the market, handling all of the product as selling agents, and in addition, taking toll for refining all of the product, to a rather benevolent organization, with market-stability for its chief end and aim, the whole to be submitted to Government scrutiny before the

details are adjusted. Meanwhile the market is in a rather disorganized condition. The foreign visible supply of copper has increased during the past two weeks about 2791 tons, which brings the foreign accumulation up to 236,864,000 lb. The November increase in foreign surplus was 14,304,640. If the present position in copper is to be improved, the decrease in surplus on this side must exceed these figures. Before the market setback caused by the Standard Oil decision, large sales were reported. Recently the metal market has suffered and there are bear rumors. Copper, it is said, will be sold at prices which will make production unprofitable for many mines and bring Washington into disfavor for interfering with plans.

MEXICO.

Aurora y Anexas. — La Blanca. — El Tajo, Jalisco. — Guadalajara. — Chamela Railway. — Zacualpan. — A. S. & R Controls Anganguero. — Oaxaca. — Onyx Development.

The La Aurora y Anexas company, owning mines to the east of the properties of El Oro Mining & Railway Co., at El Oro, State of Mexico, called a general meeting of shareholders to consider whether development work should be started once more. The meeting was represented by 1946 shares out of 3500. The important discoveries made in the El Oro camp by recent development work, have led the directors to believe it worth while to sink the shaft to a total depth of 500 ft., and drive cross-cuts. The owners of the La Blanca mine, at Pachuca, are placing orders for machinery for the mill that has been planned; 8 Pachuca tanks have been ordered from Grothe & Carter. These will be the largest yet built (60 ft. high by 15 ft. diam.). They will be built by the Hammond Iron Works, of Warren, Pennsylvania. The plant will include 6 Dorr classifiers, and 3 Dorr pulp-thickeners; 6 tube-mills of Krupp manufacture have also been ordered, that will be 4 ft. diam. by 20 ft. long.

The building of the Guadalajara-Chamela line is an assured fact. Construction will start in January beginning at La Vega, on the Ameca branch of the National lines, about 43 miles from Guadalajara, thence extending to the Pacific port of Chamela. It will open a rich mining zone and will be an important feeder to the National lines.

The Tajo Mining Co., San Sebastian district, Jalisco, is adding 10 stamps, 2 concentrating tables, and 8 sand and slime-tanks to its mill. Within another year further additions to the plant will be needed. Arrangements are being made to run the mill and air-compressor plant by water-power.

The Seguranza Mining Co., operating the old Coronas company's property in Zacualpán, is waiting for electric power to start its 100-ton mill. The main adit which has been driven during the past year, recently cut the vein at 245 ft. below the upper level. At this point the vein has a width of 36 ft., and as far as it has been tested the ore is high grade. George A. Waddel is president of the company. The Cinco Estrellas Mining Co., a close corporation operating a gold-silver property at Pinos Zacatecas, has just completed the erection of 10 additional stamps, making a total of 60. The capacity of the mill is 125 tons per day. The mill is equipped with a cyanide plant having straight percolation and decantation, sliming not being considered necessary.

The American Smelting & Refining Co. has recently acquired control, by lease, of the famous old silver mines of Anganguero, Michoacán. These mines have been shipping an average of 200 tons per month of high-grade ore to the Aguascalientes smelter. It is stated that the American Smelting & Refining Co. is arranging with the Mexican Light & Power Co. to run their power-lines into the camp, from the El Oro, only a few miles distant. The mines will then be equipped with modern machinery. L. R. Budrow, the former superintendent, will be retained.

The Teziutlán Copper Co., the owner of the Ocotes mines in Oaxaca, is said to be making arrangements for the erection of plant for treatment of pyritic ores by a new process, the rights of which were purchased by R. S. Towne. Great secrecy has been maintained in regard to it. The Natividad Mining Co. is negotiating a large loan with a local bank

to complete its cyanide plant and to erect other machinery. The Natividad mine has been one of the great producers of the State, and has been worked almost continually for 75 years, paying dividends steadily for a long time. The present policy is to suspend dividends and expend proceeds in developing the mine and improving the plant. The first export shipment of onyx from Oaxaca was made recently from the Magdalena quarries, several hundred tons being sent to New York.

GOLDFIELD, NEVADA.

Consolidated Report.—Development in Mohawk and Clermont.

The official report of the operations of the Consolidated company for the month of October shows a total production of 20,137 tons of ore containing \$794,420, or an average of \$39.45 per ton, all of which was treated by the company mill with an average extraction of \$37.28 per ton or 94.49%. The total net profit from this production was \$554,780, or \$27.55 per ton. Despite a reduction in tonnage owing to the loss of the Combination mill, the total profits showed a substantial advance due to high-grade ore produced in development in the Clermont workings. From this point and in development alone the production was 2301 tons containing \$225,905, an average exceeding \$98 per ton. New development by the company during the month amounted to 3743 ft., and is reported as usually successful, especially on the Mohawk 600 and the Clermont 750 and 900-ft. levels. Total operating costs, including mining, development, transportation, milling, office, and general expense, were \$6985 per ton including an extra charge for development in preparing for increased milling capacity, there having been 1303 ft. of this work more than in the preceding month. The caved area of the Hampton stope is being opened at the 230 and 280-ft. levels, and at the latter ore has been followed some distance south. Good results have been obtained in opening the old lease stopes north on the Mohawk, and ore is exposed in three cross-cuts in the foot-wall of the main ore-shoot at the 600-ft. Mohawk level. A large tonnage of good ore was broken in the Red Top during the month. For 220 ft. the south drift of the Clermont has exposed ore averaging \$170 per ton continuously and from this drift another has opened ore of similar character for 80 ft. on a cross-vein. The 900-ft. level has been in good ore for 320 ft., but both faces are now poor. No ore has yet appeared in the 1000-ft. level, which is being driven rapidly to the west.

SALT LAKE, UTAH.

Boston Con.—Utah Merger.—Utah Copper Sued.—Ohio Mill Started.—Ely Investments.—Silver-Lead Ore in Demand

A conference regarding the proposed consolidation with the Boston Con. and Utah Copper is being held in New York. The mines jointly are producing in excess of 7,000,000 lb. of copper each month. Utah Copper has worked some of its steam-shovel pits close to the end lines of Boston Con., and it would be greatly to its advantage to control Boston Con. properties. The rate of exchange proposed is $2\frac{1}{2}$ shares of Boston for one share of Utah Copper; as this is the third and final proposition made by the Boston company, it is a matter left entirely to the Utah Copper directors to accept or reject. E. A. Wall, formerly the largest individual shareholder in Utah Copper, has sued that company for \$1,290,000 damages for alleged extraction of ores from his Starless group. While in the Utah Copper he was very much opposed to the management and finally disposed of his entire holdings for some \$3,000,000. He is a large shareholder in Boston Con., and is opposed to a consolidation. In his complaint he bitterly attacks Utah Copper and asks for an injunction to prevent further operations and payment of dividends until his claim is settled. Mr. Wall originally owned the Utah Copper ground.

Ohio Copper is now running the first section of its mill at full capacity. Owing to the character of the ores Colin McIntosh reports that it is easy to reduce from 700 to 750 tons per day. This indicates that the mill will be able to treat 3000 tons per day, though planned for 2250 tons. A

fine discovery has been made on the Elvina vein at a depth of 500 ft. The ore carries 4% copper, 25% iron, and some gold and silver. This will be connected with the chute to the Mascotte tunnel. The mine is now sending 1000 tons of ore per day to the mill.

Samuel Newhouse and Windsor V. Rice have become interested in Ely. A group of claims between the McDonald-Ely and the Ely-Calumet have been acquired and will be incorporated under the name of the Ely Centennial. A force of men has been started on development and a tunnel is being driven at a point which will give them a depth of 500 ft. on the property. Five parallel veins cut across the ground from east to west, and a number of 'blow-outs' on the surface show silver, lead, gold, and copper in liberal quantities. The tunnel is within a short distance of the Nevada Northern road, and little expense will be entailed in opening the ore deposits. Some of the ore has been tapped by the tunnel and as it is direct smelting ore the Steptoe plant is dickering with the company for a contract to treat the output. Thomas Kearns has just returned from Ely and Duck Creek, accompanied by C. E. Allen, mine superintendent of the United States Smelting Co. They inspected the Success mine, which is shipping silver-lead ores to the local smelters. The object of the inspection was to ascertain what amount of ore could be produced, as the United States company is anxious to make contracts for ore of this character. They arranged for resumption of work at the McDonald-Ely, which is owned by Davis Keith, Thomas Kearns, E. A. Wall, and D. C. McDonald.

BUTTE, MONTANA.

Development Active.—Deep Shafts the Rule.—Everybody Busy.

More development is being done in the Butte district than at any time in a number of years. The Amalgamated is sinking a new working shaft on the Gagnon mine, to take the place of the old incline shaft which is 2300 ft. deep. The new opening has reached a depth of 360 ft., and will be carried down to 2300. The main shaft of the Leonard mine, now 1800 ft. deep, is also being deepened, as is the Mountain Consolidated shaft of the Anaconda company, which is now nearly 2900 ft. deep. The deepest shaft in the district is the Diamond of the Anaconda company, which has a depth of 2956 ft., 600 of it having been sunk during the past year. The Belmont, another Anaconda property, has reached a depth of 1190 and sinking is still going on. The Belmont is a large 4-compartment shaft. It is understood that when completed it will be used as the main working shaft of the Anaconda and other hill mines. The Amalgamated is also sinking a shaft on the Badger State, a Boston & Montana property, which carries the western extension of the Jessie vein of the North Butte company. The shaft of the West Gray Rock, a Butte & Boston property, has been sunk 400 ft. during the present year, making it now 1100 ft. deep. Two hundred feet have been added to the depth of the Little Minah shaft of the Parrot company, and it is now 1200 ft. deep. The Moonlight shaft, a Washoe company property, was sunk from the 1300 to the 1500-ft. level this year. Altogether the Amalgamated company did 141,858 ft. of new work in the past 12 months, including shafts, drifts, cross-cuts, and raises.

The North Butte company has also done an enormous amount of work, and is still engaged in developing. With the exception of the work on the Granite Mountain shaft all the work is driving and cross-cutting. The Granite Mountain is being connected with all the levels of the North Butte and the shaft is being raised from different levels toward the surface. The Butte Coalition company has been developing steadily since it began operating the former Heinze mines. Both the Tramway and Rarus shafts are being sunk deeper, the former being 1900 ft. deep, and the latter 2200. The Tramway will be sunk to the 2200, and another 100 ft. will be added to the Rarus. Half a dozen new levels have been opened from the Tramway, and several great mines have been developed by the Coalition company.

General Mining News.

ALASKA.

(Special Correspondence).—Another lot of about 2500 tons of ore is ready for shipment at the Jumbo mine near Sulzer.—An examination of the Cuprite property is being conducted by W. L. Polson, of Ketchikan, with a view to its development on a large scale.—The barge at the Goodroe mine, at Karta bay, is now loaded and ready to

Alaska Perseverance, Juneau, Alaska.

sail with about 2700 tons of copper-gold ore.—Diamond-drill prospecting on the Jumbo extension by the Tye Copper Co. is said to be meeting with good success.—A preliminary survey of the wagon-road to the Unuk river mines has been made.—The shaft at the It mine is now down 175 ft., and a drift from this level has broken into high-grade ore.

Ketchikan, November 23.

ARIZONA.

COCHISE COUNTY.

A body of high-grade ore was opened by the raise on the 1250-ft. level of the Denn-Arizona property. A station has been cut on the 1350-ft. level and a drift started on the ore which will be driven to the fault found on the 1250.—Cross-cutting has been resumed on the 1500-ft. level of the Junction shaft of the Calumet & Arizona company driving toward the Briggs workings.—A 30-ton shipment of 50% matte was forwarded from the smelter of the Arizona United Mining Co., at Johnson, recently. Several minor changes have been made at the plant and 8 tons per day of matte are being produced.—The Empire company is opening some good ore at its property in the Dragoon district and will install machinery for power in the spring.—Operations have been resumed at the property of the Fairview Mining Company.

GRAHAM COUNTY.

The Arizona Copper Co., Ltd., is installing a briquetting plant at its smelter at Clifton. By briquetting of the concentrate the company expects to greatly increase the output of the blast-furnaces.—Several test runs have been made at the new mill at the Gold Belt mine in the Clifton-Morenci district and a few minor changes are being made. If this proves successful it is probable that a mill will be erected on the New York-Arizona property adjoining.

MARICOPA COUNTY.

Work has been resumed on the Finance group near Vulture, the ore taken out being stored for shipment to the Oro Grande mill.—At the Montrose group the shaft is down over 250 ft. The work will be continued to the 500-ft. level before the company commences cross-cutting.

MOHAVE COUNTY.

A station has been cut on the 500-ft. level of the Goldbug mine, in the Weaver district, and a cross-cut started to the vein. If the ore proves of as high a value on this level as those above, a mill will be erected at the property.—The main shaft of the Horseshoe mine, at Cerbat, is down 300 ft., and a station cut at that point. A cross-cut will be

driven to open the three veins which are known to exist on the property.—Five feet of high-grade ore was opened by the shaft at the Cyclopic mine.

YAVAPAI COUNTY.

Operations have been resumed at the Octave mine, at Octave, and a stockholder's meeting called for December 12 to outline the method of work. At the Joker shaft some excellent ore has been opened.—The shaft at the Tucker property, east of Octave, is down 50 ft. on the vein.—The Nevada-Arizona Copper Co. has installed a third churn-drill at its property north of Hillside and is building a wagon-road to the mine.

YUMA COUNTY.

A shaft has been started on the foot-wall of the vein on the Bowyer property, at Quartzsite, a contract having been let for the first 100 ft. Assays of ore taken near the surface averaged \$7 gold per ton and 11% copper.—The custom mill which W. E. Scott has just completed at Quartzsite is to make its initial run on 30 tons of high-grade ore taken from his claims in that district.—The Valensuela Copper Co., in the Quartzsite district, has struck considerable water in the bottom of the shaft at the 900-ft. level and will install heavier pumping machinery in the near future.

CALIFORNIA.

AMADOR COUNTY.

A dividend of 20c. per share was recently paid by the Argonaut Mining Co., at Jackson. Forty stamps are dropping in the mill.—A number of stockholders of the Amador Gold Mining Co. visited the Bay State and Rhetta mines owned by the company at Plymouth and as a result of the good condition of the mines it is probable that a 50-stamp mill will be erected within the next six months.—Twenty stamps are dropping in the mill of the Original Amador Mining Co.—The Kennedy Extension Gold Mining Co. has brought suit against the Argonaut Gold Mining Co., operating at Jackson, to recover \$200,000 damages for ore claimed to have been extracted from the former's ground by the latter company.

CALAVERAS COUNTY.

The adit at the Ariel mine, near Mokelumne hill, is in 170 ft., and has cut two veins. It will be continued till it opens the third vein which outcrops on the surface.—The workings at the North Star gravel mine are being re-timbered preparatory to the resumption of work.—Thomas Ewing is sinking a 2-compartment shaft at the Tulloch mine south of Angels and work will be started soon re-modeling the mill.—Operations are to be resumed at the Petticoat mine at Rail Road Flat.—The Dolling Gold Mining Co. is sinking a 2-compartment shaft at the North Star mine and a 40-stamp mill will be erected at the property.

INYO COUNTY.

The cross-cut on the lower level at the property of the Bishop Creek Gold Co., on the middle fork of Bishop creek, opened an 8-ft. vein of \$34 ore. The average assays of samples of ore taken from all portions of the mine have been over \$10 per ton. Paul E. Lodge, the manager, is authority for the statement that the company will erect a 50-stamp mill in the spring.

NEVADA COUNTY.

The Champion group of mines in the Nevada City district has been sold to a new company known as the Champion Gold Mining Co. The sale includes a number of the oldest and richest mines of the district, among which are the Champion, Providence, Wyoming, Merrifield, Home, Cadmus, Nevada City, and Spanish mines. George E. Fitzgerald is at the head of the company.—Schroeder & Torpie are to build a small mill on their claims in the Grass Valley district. A drift, now being run on the vein, is opening a good grade of ore.—Sinking has been started on the Colling ranch near Rough and Ready. Considerable rich placer ground was worked here in early days and several veins of quartz have been slightly prospected.—Work has been stopped for the winter on the Fairview mill near Washington on account of the heavy snow.—Lucian

Kahn has secured a bond on the Last Chance property near Maybert and will commence active work at once.

PLACER COUNTY.

A 10-stamp mill is being erected at the Crater mine in the Ophir district by W. P. Hammon.

SHASTA COUNTY.

The rich vein at the Uncle Sam mine, eight miles west of Kennett which was lost a number of years ago, has been found and shipping will be resumed on a large scale. L. C. Monahan is superintendent.—At the Clipper mine of the Carnegie Group of Mines Co. in the same district, rich ore has been opened and the company is to erect a 20-stamp mill. Fred Bowler is manager.—The clean-up of the plates at the Milkmaid mine in French gulch for the last 17 days in November resulted in \$8500 worth of bullion.

SIERRA COUNTY.

The adit at the Secret Ravine property in the Alleghany district is in 200 ft. and is expected to open the channel in a short time. Clifford Weldon is in charge of the property.—At the Oriflamme, on Chipps ridge, the adit is in over 200 ft. and has cut two veins. There still remains about 200 ft. of driving to open the main vein. C. C. Ward is manager.

TRINITY COUNTY.

Paulsen Brothers and Siligo & Wilson, operating leases on the Knob mine at Deadwood, are both mining ore that assays about \$500 per ton.—At the Lappin the mill is running 20 hours per day on good ore.—The mill at the Brown Bear is running on ore taken out by lessees.—Work has been suspended temporarily at the plant of the Trinity River Tunnel Mining Co., the force of the water being so great as to move some of the machinery. The damage is estimated at about \$2000 and repairs will be made at once.—R. A. Skinner, superintendent of the Mountain Boomer mine on New River, brought a \$10,000 gold bar to Weaverville.—The Wilson Hill mine near Knob has been bonded to Ross G. Beronda. The property is supposed to contain an extension of the Midas vein and has been worked intermittently for some time though no extensive orebodies have been opened. An 8-hp. Graupner mill and concentrator is to be installed at the Blue Jay property, near Carrville, the power being furnished by the Headlight plant. The shoot at the Blue Jay is 18 in. wide, and has been followed to a depth of 200 ft.—An arrastre is to be erected on the Belli property. The vein here is from one to four feet wide and the ore free milling.

TUOLUMNE COUNTY.

The electric current has been turned on at the Draper mine, all the machinery now being operated by electricity.—A suit to quiet title to a tract of land in the western part of the county has been instituted by Jay A. Rydberg and E. A. Rydberg against the Don Pedro Gold Mines Company.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—An orebody 2' ft. wide has just been cut by the winze that is being sunk on the Independence vein from the Tobin adit level. It assays \$70 per ton in gold, silver, and lead. C. L. Tingle is manager.—A shipment of 20 tons of smelting ore was sent out from the Santiago mine last week which netted \$2100. The ore was taken from a winze that is being sunk from the fourth level. William Rogers is manager.—Weaver & Son, operating the Kirtley mine on Leavenworth mountain, have just shot into an 8-in. streak of silver-lead ore that is worth from \$43 to \$47 per ton. This mine has produced over \$500,000 worth of ore, but remained idle for 15 years previous to a few months ago.

Georgetown, December 3.

(Special Correspondence).—A 3-ft. vein has been cut on the 13th level of the Sun and Moon mine on Seaton mountain. The ore is of a smelting character and one carload per day is being shipped, the returns being \$40 to \$50 per ton. O. W. Lowell is manager.—The Silver Horn mine has been taken under a two-year bond and lease by D. McDougall and associates.—Charles DeCamp, manager for

the Colorado Quito Gold Mining Co., is employing a force of men in cleaning out the Quito mine workings, and shipments of both smelting and concentrating ore will be started during the next two weeks.—The output from the Saratoga property now averages 30 tons per day of a smelting ore. The net earnings for the last three months have averaged \$800 per week. John Owen is manager.—Wright & Pellam, leasing on the Treasure Vault mine, made a 20-ton shipment last week to the Modern smelter at Utah Junction.—New mine buildings have just been constructed at the holdings of the Princess Alice Mining Co., on Fall river. J. F. Kaminky, the manager, states that early the coming week a modern concentrating mill will be started.

Idaho Springs, December 4.

GILPIN COUNTY.

About 20 tons of milling ore which had been stored on the dump of the Perigo mine from the lease of Bone & Eva, was treated at the Perigo mill and several tons of smelting ore shipped to Black Hawk.—A new 100-hp. boiler has been installed at the Gold Chollar mine in Prosser gulch.—

Perigo Mill, Gilpin County.

The cross-cut at the Tregay & Co. lease on the War Eagle mine at Gilpin, opened two feet of copper-iron ore and several stopes will be opened preparatory to shipment to the smelter.—The Slide Mining Co. has unwatered its property and will ship a carload of ore to the Modern smelter. M. A. Harris, of Russell Gulch, is in charge of the work.

LAKE COUNTY.

A rich shoot of silver ore has been opened by lessees on the old Ella Beeler property, in Iowa gulch. The vein is a foot wide, and assays from the richest portion have been over 75% silver.—Operations are to be resumed at the Big Four mine on Breece hill. A large amount of high-grade ore has been shipped from the property in the past and it is expected to become an important producer when opened on a large scale.—The power company has completed its lines to the Sugar Loaf district and a number of the mines are changing their power equipment. A complete plant is being installed at the Sagnache adit.—L. R. Johnston, operating the Iron Mask mine, at Leadville, has opened several good orebodies and is shipping sulphide ore.—The Connors Bonanza group has been taken over by the Elk Mountain Mining & Leasing Co., and the old workings are being re-timbered. Terry Connors is manager.—Operations have been resumed in the Printer Boy mine by a number of lessees.

OURAY COUNTY.

The report of the Camp Bird, Ltd., recently issued, states that the gross production was \$2,230,000, dividends for the fiscal year, \$964,000, and \$2,360,000 profit in the ore blocked out. A new discovery has been made on the fifth level, opening a body of ore that assays from \$50 to \$70 per ton.—A 6-in. vein of high-grade silver ore has been opened in the El Mahdi mine for 50 ft., and a stope started.—

Jackson & Weatherly, operating the Wedge property under lease, shipped a car of ore and are getting the mine in shape for a heavy production.

SAN JUAN COUNTY.

Operations have been resumed at the Old Hundred mine, in the Silverton district, which was shut down two years ago. There are 30 claims in the group which is equipped with an excellent mill and power plant.

SUMMIT COUNTY.

Operations have been temporarily suspended at the Wellington mill owing to the shortage of railroad cars.—The ore at the Sallie Barber property is being stored as the roads are too bad for hauling.

TELLER COUNTY.

Love & Thirkell, sub-leasing on the second level of the American Eagles mine, have opened a body of ore that assays from \$40 to \$80 per ton. The last few feet of the work has been in extremely rich ground, the ore being sacked in the stopes for shipment.—The Joe Dandy Mining Co. is re-timbering the shaft at the Eclipse No. 1 claim and has let several leases on blocks of ground in the Eclipse and Jo Dandy claims.—S. N. Simmons has secured a two years' lease on a portion of the Rittenhouse Gold Mining company property and is opening good ore on the 500-ft. level.—The quarterly report and dividend checks for ¼c. per share were mailed to the stockholders of the Doctor-Jack Pot Mining Co. on December 1. The report states that a new electric compressor has been installed at the Davenport shaft, that nine sets of lessees are shipping ore, and the suit against the Work Mining & Milling Co. over apex rights will be brought up next January.—The report of the Gold Dollar Mining Co. for the past quarter stated that the company had a surplus of \$13,244 on hand, but that no dividend would be paid as it was the intention of the management to resume work on company account, and that a cash balance would be necessary in starting this work.—During November the lessees operating on the El Paso properties shipped 2500 tons of ore. That from the mine assayed from \$28 to \$30 per ton, and that from the dump \$6 to \$8.—The Roosevelt drainage tunnel was advanced 298 ft. the past month making a total of 11,705 feet.

A promising ore-shoot has been opened by lessees on the 325-ft. level of the Hull City shaft of the Vindicator Consolidated Gold Mining Co.—The output of the mines of the Cripple Creek gold mining district for the month of November totalled 50,215 tons with a gross bullion value of \$1,284,487. Local mills treated a better grade of ore, and the average value of the smelting ore was \$1 per ton higher than the preceding month, and the general average of all grades treated was \$21.67 as compared with \$20.30 for October.—As compared with the tonnage of October there is a decrease approximating 4500 tons and about \$7100 in valuation.

| Plants. | Tons Treated. | Average Value. | Gross Value. |
|------------------------|---------------|----------------|--------------|
| Smelters | 4,125 | \$66.00 | \$272,250 |
| Golden Cycle Mill..... | 25,380 | 20.40 | 517,742 |
| U. S. R. & R. Co..... | 13,010 | 22.00 | 286,220 |
| Portland G. M. Co..... | 9,000 | 19.00 | 171,000 |
| Gold Issue Mill..... | 1,800 | 5.00 | 9,000 |
| Isabella | 1,750 | 4.50 | 7,875 |
| Trilby Mines Co..... | 1,650 | 6.00 | 9,900 |
| Wild Horse Mill..... | 1,500 | 5.00 | 7,500 |
| Gaylord Mill | 1,000 | 3.00 | 3,000 |
| Total | 59,215 | \$21.67 | \$1,284,487 |

IDAHO.

OWYHEE COUNTY.

The Dewey Homestake Mining Co. has been organized to open the Dewey Homestake mine near Silver City. There is a large outcrop on the property and a shaft has been sunk 300 ft. on the vein. George Schlack is superintendent.—The north drift at the Banner mine cut the vein beyond the fault showing quite an improvement in the ore.

SHOSHONE COUNTY.

Fifty cars of native silver ore have been shipped from the Caledonia mine near Wardner netting the company \$5000 per car. The orebody containing this rich ore was opened recently on the lowest level of the property.—The shaft of the North Bunker Hill Mining Co. cut an orebody that assayed 13% lead, 7% copper, and 3 oz. silver per ton at a depth of 100 ft.—The adit at the property of the Index Mining & Milling Co. is in 600 ft., and it is expected to cut the vein about the first of the year.—The vein at the Black Bear Fraction mine was cut by the adit when in 700 feet.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—A number of companies are at work developing the deep ores in the Galena field, among the more recent of which is the Big Six Co., on the Murphy land. A drill-hole was put down 240 ft. a number of years ago cutting ore below the 200-ft. level, but as deep ore was then untouched and ore was sold at a low price, it was never opened. The new company drilled several holes in the vicinity of the former find and verified the old record, finding rich ore between 240 and 280 ft. A 250-ton mill will be built, the shaft sunk 280 ft., and later deepened to 350 ft. The ores are of the sheet variety.—The Galena camp is being materially extended to the south by the development work of the Clermont Mining & Milling Co., under the management of Joe Fahlenbach. This company has been prospecting and developing a 500-acre tract on Shoal creek and has demonstrated some good runs at varying levels, the upper from 40 to 60 ft., a second from 150 to 200 ft., and a third from 222 to 300 ft. Several shafts have been sunk by the original company and also by sub-lessees. The company is just completing a large new plant and will soon be ready for operation.—Frank Nicholson is now developing a 40-acre lease on the Murphy land, and has bought a 200-ton plant of McNeal & Co., from the Joplin camp, for the new lease. This tract has two shafts in ore at 155 ft.—The Diplomat Mining Co. recently secured a 10-acre lease from the Galena Lead & Zinc Co., including the old Mayflower mine.—The New England Mining Co. has just purchased a 440-acre tract from the O'Neal heirs and is preparing to prospect the ground.

Galena, November 13.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The Cliffwood Mining Co., on the Deerstone tract, is beginning the erection of a 150-ton mill. Three shafts are in ore at a depth of 180 ft.—A shaft on the Van Hoose 40 acres opened over 20 ft. of ore at the 143-ft. level.—Among the more promising new properties between Carthage and Alba is the I. C. Hodson land where three drill-holes have cut ore at 240 ft., the drill penetrating a 38-ft. face, and the Tanger land where a shaft is being started. The Consolidated Troupe Co. has just completed a 300-ton mill on the Hallwood farm and is sinking a new shaft.—On the Continental ground also west of the city, the new Clarke mill, formerly the Buckeye taken from Fairview cemetery, is now producing.—The Temagami mine, also on the Continental land, is working at a depth of 200 ft. where a much larger percentage of lead is being taken out than zinc, which is unusual in this district at that depth.—The Mandarin mine, at Chitwood, is being re-opened and an excellent body of ore is in sight, the best in the history of this mine.—A shallow discovery, resembling the old time finds, has just been made in the Zincite camp by Dix & Co. The ore was found at 50 ft., partly in large chunks and partly finely disseminated through the gangue.—Two excellent mines are being operated on the Old Dominion land at Smelter Hill, the Big Eight, and the Damphino. The ore is unusually rich. On a recent run of 862 tons through the mill, 86 tons of zinc and five tons of lead were procured.—Owing to a reduction of royalty on the city land near Fairview cemetery, the Adirondack company has undertaken the development of the lower sheet levels. The lower run is found to occur from 188 to 218 ft.—The old Hyde Park mine in the

Prosperity camp has been leased by Frank Nicholson, and will be put in operation as soon as the ground is drained.—The mill is modern and practically new with a capacity of 250 tons.

Joplin, December 4.

MONTANA.

SILVER BOW COUNTY.

(Special Correspondence).—The Butte & Superior Copper Co., Ltd., owning one mile of the Rainbow lode, adjoining the Alice group on the east, in Butte district, has opened the property to a depth of 1600 ft., the development from the shaft showing the lode to be about 200 ft. wide, between granite walls, the ore-shoots being from 12 to 60 ft. wide. The ore is a zinc blende in quartz; it carries 25% zinc, 5 to 30 oz. silver per ton, 60% silica, and only about 2% iron. The hoisting is done by steam power, and an electric-driven Allis-Chalmers air-compressor is being installed which has the capacity of 2500 cu. ft. of free air per minute. To treat the ore a concentrating mill of 500 tons per day capacity is being constructed, the equipment for the greater part having been purchased from the Allis-Chalmers Co. The construction work will continue through the winter. The company has arranged to operate the Basin concentrator on its ore during the period required to construct the new mill. The operation of the Basin plant will begin in January, and it is stated that 10,000 tons per month will be shipped to it. D. F. Haley, formerly with the North American Lead & Zinc Co., will have charge of the Basin mill. R. M. Atwater, general manager for the company, states that a 10-years contract has been entered into with the American Metal Co., Ltd., whereby the latter will take the concentrate. M. W. Atwater is superintendent of the mine.—The Davis-Daly Copper Co., for which Alfred Frank is superintendent, has reached a depth of 1851 ft. in its Colorado shaft, situated below Park street, near the centre of Butte. At the shaft is a 100-ft. steel head-frame and a first-motion, flat-cable, steam hoist, Webster, Camp & Lane make, capable of operating to a depth of 2000 ft. There are three air-compressors—a Nordberg, 22-drill capacity, electrically driven; a Franklin electric of 10-drill, and one of 6-drill capacity, steam-driven. Mr. Frank states that a large tonnage of ore is exposed. The company ground extends 4000 ft. west and 1400 ft. east from the shaft. On the 1400-ft. level is said to be an ore-shoot 700 ft. long. Driving has been commenced in ore on the 1500-ft. level, and a station has been cut at the 1800. The veins on the property average 20 ft. wide, 15 ft. of which is pay ore. This is said to contain $2\frac{1}{2}$ to 4% copper, 6 oz. silver, and 50c. gold per ton. The concentrator at Basin belongs to allied interests, and one part will run on Davis-Daly ore, handling 500 tons per day. The strike of the switchmen on the Northern Pacific has cut off the coal supply of Butte and in consequence the Moonlight and Parrot mines of the Amalgamated company have been forced to shut down temporarily.

Butte, December 4.

NEVADA.

ESMERALDA COUNTY.

(Special Correspondence).—An extension of lease on the 20-stamp mill of the Nevada Goldfield Reduction Co. has been secured by the Combination Fraction company, and it is announced that operations of both mine and mill will be resumed at once. Development work, although upon a reduced scale, has been in progress almost continuously since the announcement of the suspension of operations was made.—Local operators have secured a lease upon a portion of the company workings of the C. O. D. Consolidated, including the plant at the main shaft on the Gold Bar claim where a considerable tonnage of low-grade, free-milling ore is exposed.—Foreclosure proceedings have been instituted in the District Court against the Diamondfield Black Butte Consolidated company to force a sale of the property and obtain judgment for the chief creditors who have assigned their claims, amounting to some \$16,000, to the Registration Trust Co., of Goldfield, with instructions to reorganize the concern upon an assessable stock basis. Lessees are still taking some rich ore from these claims.

—The shaft of the Thomas lease, on Columbia mountain, is following a strong vein on the incline, carrying a foot of shipping ore in 8 ft. of vein-matter, and will drive a raise from the old company adit for air connection while driving on the vein at the 160-ft. level.—William MacKay and associates are taking out rich ore from the original St. Ives shaft on territory of the Goldfield Merger Mines Co. Work has been started on the south end of the Booth by lessees who are seeking the extension of the Red Top vein while others will drive for the same vein system on the Night-hawk group.

Goldfield, December 6.

LINCOLN COUNTY.

A raise has been started from the 100-ft. level to the surface of the Pioche Metals property and when completed the gasoline hoist of the company will be installed and sinking commenced.—A rich vein was opened by the cross-cut on the 500-ft. level of the Golden Prince mine

Goldfield District.

when 230 ft. from the shaft. Some rich specimens of wire-silver have been taken from the recent discovery.—Hoisting equipment has been shipped to the Gold Chief Mining Co., at Pioche, from Salt Lake, and the company is considering erecting a mill in the spring.—About 50 tons per day are being shipped from the Prince Consolidated at Pioche.

NYE COUNTY.

Lessees on the Jim Butler ground are all stoping ore. On the Star lease the cross-cut has opened several stringers of quartz from which a good grade of ore is picked. The California lease is in good ore on the 150-ft. level.—On the 540-ft. level of the Silver Top workings of the Tonopah Mining Co., the west drift from the south cross-cut is being driven on a 4-ft. vein thought to be the extension of the main vein beyond the fault. In the Mizpah workings the south cross-cut from the southwest drift on the 400-ft. level is opening a body of low-grade milling ore.—Operations have been resumed at the Belmont, the repairs to the foundation of the compressor having been completed.—Considerable prospecting is being carried on at the 800-ft. level of the MacNamara.—The McGhan lease on the Blue Jacket at Round Mountain is in good ore and the lessees are storing it on the dump till they get enough for a mill-run.—The Solid Gold mill has again been started on ore from the Daisy mine.

WHITE PINE COUNTY.

The pit of the Nevada Consolidated at Copper Flat is attaining such a depth that getting out the ore from its lowest point is becoming quite a problem. Only two cars can now be hauled at a time from the lowest point in the pit to the main line of the railroad. There is, of course, plenty of ore available along the sides of the pit, but the bottom is still entirely in ore and the management must soon either cut into the lower levels with an adit driven from quite a distance or use locomotives of some type capable of climbing heavier grades than those now in use. Only about 240 ft. now intervenes between the bottom of the new Giroux shaft and the top of the raise from below. The miners are making from $6\frac{1}{2}$ to 7 ft. per day in the raise.

—Great satisfaction is expressed in the district over the positive announcement of the immediate commencement of construction of the new railroad, to be known as The Ely Route, between Ely and Goldfield. Leaving Ely, the road will traverse nearly the entire mineral belt of the district. On the Giroux estate, a deep cut must be made, a portion of which will be through the characteristic porphyry ore which has given this district its reputation. The road will be by far the shortest route from the East to southern Nevada when taken in connection with the Western Pacific and Nevada Northern. It will open a new and desirable route from Salt Lake to Los Angeles by way of Ely and Goldfield and will assist in the development of a great mineral and ranching country in central Nevada.—The Ely Silver, Lead & Copper Co. is to resume work at its holdings 12 miles east of Ely.—The Steptoe Valley Smelting & Mining Co. is to add a lead furnace to its plant and will treat the lead ores of the district.

UTAH.

JUAB COUNTY.

(Special Correspondence).—A great deal of attention is being paid to the operations in the eastern portion of the Tintic district. In such dividend payers as the Colorado, Sloux Consolidated, and Iron Blossom, the ore deposits in the upper levels are being worked out. Engineers are beginning to believe that there is a rich stratum of ore that passes through that district near the surface, as no deep working in these properties have brought encouraging results. A depth of 1300 ft. in the Iron Blossom and 1100 ft. in the Beck adit have failed to disclose a commercial grade of ore in paying quantities. Moving farther to the east of these properties a small deposit has been opened in the East Tintic Development ground from 100 to 300 ft. from the surface. Just recently a large deposit of talc has been cut at a depth of 200 ft. in the Gruttl ground, and on the hanging wall of this formation 2 ft. of silver-lead ore has been exposed. John Bestlemeyer, one of the pioneers of the camp, is manager of this property, and he intends to sink to greater depth at once, as the ore is dipping downward, and some of the greatest deposits have been found below the talc in that district.—Walter Fitch, president of the Chief Consolidated properties, in Tintic, reports splendid progress in the development of this ground. They began in October extracting some silver-lead ores from a depth of 1700 ft. This work has been continued below the 2000-ft. level, and during November an extraction was made that will net the company in the neighborhood of \$25,000. Drifts are to be extended under the town of Eureka, where this company has secured all the mineral rights, and Mr. Fitch is confident that his company will be able to mine a first-class grade of ore for a number of years to come. The company owns a large block of ground adjoining the Centennial-Eureka mine, owned by the United States Smelting R. & M. Company.

Tintic, December 3.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The shipment of 11,616 tons from the Mother Lode mine of the British Columbia Copper Co. made a new record in high shipments for the week, while the output of the Oro Denoro mine of the same company dropped several hundred tons, on account of the crew

being reduced.—Application has been made in the Supreme Court at Vancouver that the money now in the hands of P. F. Roosa, the liquidator of the Dominion company, be paid into court, and the liquidator released on the ground that he failed to advertise for creditors. The case was adjourned for three weeks, awaiting further evidence from New York.—During the month of November the Granby plant treated over 120,000 tons of copper-gold ore, equivalent to about 31,680,000 lb. copper per annum.—The total shipments for the week from the Nelson district are rather light. The McAllister sent out a small initial shipment, the Alice made its second consignment to the Trall smelter, while the shipments from the St. Eugene were the heaviest that have been made this month.—A 20-ft. vein of good milling ore has been opened in the United mine, of the Highland-Buckeye company. J. S. Airheart is manager.—The International Coal & Coke Co., at Coleman, is shipping steadily at the rate of 2500 tons per day. The company is working 215 coke ovens. The company recently sold a couple of hundred shares of treasury stock and paid off all its indebtedness, including a bond issue of \$300,000.

Rossland, December 3.

ONTARIO.

Prospecting on the surface has been concluded at the Nipissing property in Cobalt. During the past year 33 miles of trenches have been dug on the ground uncovering 24 veins of which No. 122 was the bonanza, as something over \$200,000 worth of ore has been mined from it. The vein has been traced for 670 ft. underground, having an average width of 6 in.—It is announced that Crown Reserve will pay the regular 15% dividend for the last quarter of this year, and an extra dividend of 10%.—It is reported that the interests controlling the Kerr Lake Mining Co. have secured control of the Temiskaming mine.—The cross-cut on the 60-ft. level of the Nancy Helen opened a rich stringer about 80 ft. from the Boston line.—A shaft started on a barren calcite vein on the Wyandoh property opened 3 in. of smaltite at a depth of 9 feet.

MEXICO.

CHIHUAHUA.

Luis Terrazas, Jr., J. W. Clayton, and Charles Seawell, of Chihuahua, have been granted a concession by the State Government to build a smelter at Temosachic. The concession is for ten years with exemptions from State and municipal taxes, and the concessionaires plan to erect a 100-ton plant to treat the copper-gold-silver ores of the district.—The capacity of the plant of the Rio Tinto Mining Co., operating near Terrazas, is to be doubled and converters installed, bringing the capacity of the plant up to 400 tons per day.—Eight Pachuca tanks have been ordered for the Blanca cyanide plant at Pachuca, six Dorr classifiers, and three pulp thickeners. The Pachuca tanks are the largest ever constructed, being 15 ft. in diameter and 60 ft. high.—It is reported that the American Smelting & Refining Co. is to enlarge its lead smelter at Chihuahua from 450 to 750 tons per day capacity, and to discontinue shipping lead fluxing ores to the El Paso plant.—Contracts have been let by the Palmilla company, which is building the 1000-ton mill at Parral to the Minneapolis Steel & Machinery Co. for a complete power plant and to the Allis-Chalmers company for the milling machinery.

JALISCO.

The Amajac Mines Co. has been organized to take over and operate the Refugio-Animas group, Amajac mill, Tres Estrellas mine, and adjoining claims formerly operated by Carlos Romero. W. R. Ramsdell is at the head of the company.—The Tajo Mining Co., operating in the San Sebastian district, has ordered ten stamps, two concentrating tables, and eight tanks for additional equipment in the mill. This will double the capacity of the plant.

ZACATECAS.

The Cinco Estrellas Mining Co. has completed the installation of ten additional stamps in its plant at Pinos raising the capacity of the mill to 125 tons of ore per day. H. R. Levick is superintendent.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. A. SCOTT is at Butte.

A. E. DRUCKER is in London.

D. C. JACKLING is in New York.

ALBERT BURCH has gone to Mexico.

GEORGE S. RICE has been at Chicago.

A. P. ANDERSON is in San Francisco.

L. A. GREENE has returned to San Francisco.

H. V. WINCHELL is at Spokane, Washington.

ALGERNON DEL MAR was in San Francisco this week.

W. J. ADAMS has returned from Kern county, California.

ROBERT SCHORR has gone to Denver on professional business.

FRED HELLMAN has returned to New York from San Francisco.

C. W. PRITCHETT, of Denver, was at Butte, Montana, last week.

S. W. BURBRIDGE, of Colorado Springs and Denver, is in New York.

LESTER W. STRAUSS has returned to Lima, Peru, from a trip to Chile.

R. A. F. PENROSE, Jr., has returned to Philadelphia from the Southwest.

SAMUEL NEWHOUSE has been called to Paris by the sickness of his brother.

J. FRANK BECK and THOS. NUTTAL MILLER, of the Bully Choop G. M. Co., are in San Francisco.

J. CUTHBERT WELCH is smelter superintendent for the East Butte Copper M. Co., Butte, Montana.

A. A. SMITH has resigned as superintendent for the Farah Mining Co., at Cobalt, and will go to Mexico.

DARSIE C. BARD, mining engineer, Butte, Montana, recently visited the Coeur d'Alene mining district, Idaho.

ALEXANDER LEGGAT, who was engaged for the season in engineering work in eastern Montana, has returned to Butte.

CHARLES KAMMERER is manager for the Conrey Placer Mining Co., operating three gold dredges at Ruby, Montana.

DAVID LADD, formerly with the Michigan Smelting Co., goes to Australia with the Wallaroo & Montana Smelting Company.

EDWIN J. COLLINS, of Duluth, Minnesota, sailed from Seattle on December 1, for Alaska for a four weeks' mine-examination trip.

WILLIAM KEMP, consulting mining engineer for the Calumet & Arizona Mining Co., was a business visitor to San Francisco this week.

THEODORE DWIGHT is at Guanajuato, Mexico, on business connected with the purchase of the Tajo de Dolores property by the Proprietary Mines Company of America.

R. M. ATWATER and M. W. ATWATER, of New York, are general manager and superintendent, respectively, for the Butte & Superior Copper Co., Ltd., operating at Butte, Montana.

J. B. FLEMING has completed the plant for the Globe Light & Power Co., at Daunt, California, and is now building a hydro-electric plant in the Sequoia National Park for the Mount Whitney Power Company.

S. H. BALL, formerly of the United States Geological Survey, and more recently in charge of the prospecting for the Société Internationale Forestière et Minière du Congo, has opened an office at 71 Broadway, New York, as consulting mining geologist. He is at present on professional work in New Mexico.

THE San Francisco Section of the Mining & Metallurgical Society will meet at the Palace Hotel, at 6:30 p. m., December 15.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF MINERALS—CONSTRUCTION.

A bare conveyance of minerals does not create a special and distinct estate in a technical sense; it only separates a part of the property from the remainder and the right to ownership and control of such minerals is consistent with all other rights of ownership to the surface and other parts of the land. It accordingly follows that where a mineral which has been conveyed was removed from the land, the owner of the mineral ceased to have any further rights in such land. It is also the rule that a grantee of minerals has no way of necessity over the land of a stranger to remove such minerals.

McBurney v. Glenmary Coal & Coke Co. (Tenn.) 118 Southwest. 694, May '09.

CONVEYANCE OF A SPECIFIC MINERAL—EFFECT.

Where the owner of land conveys a particular mineral by a specific term, and not by a general term, the rule is that such particular mineral alone will pass, and that all other minerals remain as the property of the owner of the land.

McBurney v. Glenmary Coal & Coke Co. (Tenn.) 118 Southwest. 694, May '09.

POWER OF STATE TO REGULATE MINERAL SPRINGS.

A State under the doctrine of police powers may regulate the use of mineral and carbonic acid gas wells and prevent waste and detriment to neighboring proprietors who procure water and gas from the same source.

Hathorn v. National Carbonic Gas Co. (New York) 87 Northeast. 504, Feb. '09.

LOCATION OF MINE—QUALIFICATION OF LOCATOR.

The United States statutes prevented the officers, clerks, and employees of the General Land Office from purchasing or becoming interested in the purchase of any public lands. But where a person while competent to make a mineral location, did locate a mine with an excessive area, and thereafter changed the boundaries of his claim so as to exclude the point of discovery, and before making a new discovery within the readjusted boundaries, was appointed a deputy surveyor of the Land Department, his claim perfected by a new discovery after his appointment was void.

Waskey v. Hammer, 170 Fed. 31, May '09.

ADVERSE MINING CLAIMS—QUIETING TITLE.

A locator of a claim in a mining district where there may be extra-lateral rights existing in favor of those owning contiguous or neighboring claims, cannot compel them in an action brought by him to assert and make proof of such rights which might exist in their favor, and that a judgment in such an action by the locator cannot be exclusive as to the rights of the parties in the ownership of such extra-lateral rights; he cannot thereby cast the difficult and usually impossible burden upon the owners of adjoining claims, whom he may name as defendants in his action, to make immediate proof of their rights, whether they know the facts conferring such rights or not, and practically to assert adverse claims to a thing before they know it exists. It is only when a claim of an adverse estate or interest is made that the owner can avail himself of the statutory remedy for determining the title to adverse claims. If the owner's title to the surface of the mine as a whole is denied on the ground of alleged failure to take some steps essential to its acquisition, then the owner can resort to the statutory remedy and require all claimants to make good their adverse claims to such title or be forever barred from doing so. But whether a vein exists underneath the surface or whether it so dips and reaches its apex within the body of a claim owned by another is always purely conjectural until the facts are ascertained by discovery and development.

Keely v. Ophir Consolidated Min. Co., 169 Fed. 601, Apr. '09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

GEOLOGY AND ORE DEPOSITS OF GOLDFIELD, NEVADA. By F. L. Ransome, assisted in the field by W. H. Emmons and G. H. Garrey. U. S. Geol. Surv., Prof. Paper, 66. 251 pages, index, ill., maps. Washington, 1909.

The appearance of this report has been awaited with much interest. Copies were available early in October, although field work had continued into November 1908. This promptness in publication stands in welcome contrast to the past record of the Geological Survey. The report itself is not less welcome. Mr. Ransome has discussed in detail and with clear insight the geology of our great gold district and has done much to elucidate the complex problems of the genesis and distribution of the unique deposits. Aside from the local interest in the structure and extent of the deposits, attention centres naturally in what he has to say of the genesis of alunite and its association with gold. Alunite, the hydrous sulphate of potassium, is so abundant in the Goldfield district and so generally associated with intense alteration of the rocks in the vicinity of the ore deposits that it has come to be considered one of the most characteristic minerals and has given name to a new type of ore deposits, the alunite-gold type. Mr. Ransome abandons his earlier hypothesis, that the ore-depositing solutions may have come from below already charged with sulphuric acid, and considers two other hypotheses. (1) The alunization of the rocks of Goldfield may have been effected by cold sulphate solutions percolating generally downward in masses of oxidizing sulphides, principally pyrite. This is rejected on the basis of its quantitative insufficiency. (2) According to the third hypothesis, which is the one favored, the ore constituents were brought up in hot solutions charged with hydrogen sulphide, a little carbon dioxide and probably alkali sulphides; the hydrogen sulphide was oxidized at and near the surface to sulphuric acid which percolated down through the warm rocks to mingle with the rising currents carrying sulphuric acid; the precipitation of the richest ores took place in the zone where the two kinds of solutions mingled, and in consequence of such mingling. Space is not available to cite the evidence for and against this hypothesis. While it lacks demonstration, it seems well sustained. The report is a substantial contribution to the science of ore deposits and an excellent example of the good work the Geological Survey can do in aid of the mineral industry.

IRON ORE DEPOSITS ALONG THE OTTAWA (QUEBEC SIDE) AND GATINEAU RIVERS. By Fritz Cirkel. Canada, Dept. Mines, Mines Branch. Pp. 147, ill., index. Ottawa, 1909.

The publication of this report comes at an opportune time, owing to the development lately assumed by the smelting of iron ores by electricity. The region discussed possesses great water-powers, a part of which could well be applied to the establishment of an iron and steel industry. After describing in detail various iron ore deposits in the townships of Hull, Templeton, Wakefield, Bristol, Grenville, and others, Mr. Cirkel concludes that many of these would yield ores which could probably be treated profitably in the electric furnace. It is stated in the report that this method of reducing the iron ores can compete with the blast-furnace for the production of pig-iron, when electrical energy can be developed at a low cost. All engineers and metallurgists interested in the iron and steel industry will read the report with interest, more especially the general conclusions which are given from page 100 to page 107.

The Copper Combination.

The Boston News Bureau has prepared the figures quoted below, which, while of course entirely theoretical, present some interesting deductions based on the assumption that the profits of the various subsidiary properties on 13c. copper will be capitalized into 6% preferred stock, and that

this preferred stock will be worth \$90. This is reported to be the basis on which the merger is to be made. Figures are also shown representing the capitalization of the additional profits to be derived on 15c. copper into 4% common stock, and assuming that this common stock will be worth \$50.

In order that the figures below may be clearly understood, the way this theoretical proposition works out must be explained. Amalgamated, for instance, has 1,538,000 shares outstanding and has an ownership in about 205,000,000 lb. of annual copper output. This copper is being produced at an average cost of about 10c. per pound, and the profits on 13c. copper amount to \$6,150,000 per annum, or \$4 per share. The additional profits on 15c. copper amount to \$2.70 per share. If the 13c. copper profits are capitalized into 6% preferred stock, and this preferred stock is worth \$90, there results an equivalent value of \$59.50 per share to be received in new 6% preferred stock and a value of \$33.50 per share in new common stock, or a total of \$93 per share. Following this same line of reasoning, there works out a value of \$47 per share for Anaconda, 84½ for North Butte, 25½ for Butte Coalition, 51½ for Utah Consolidated, 80 for Utah Copper, 30 for Nevada Consolidated, 14 for Greene-Cananea, 13½ for Superior & Pittsburg, and 119 for Calumet & Arizona.

The figures take into consideration only the present earnings of the various subsidiary properties. They do not take into consideration, as in the case of Amalgamated, the value of its timber and coal lands, and neither do the figures take any account of the great differences which exist with respect to the ore reserves of the various properties. These are all matters which will have to be worked out in conference, and explain, in some degree, why it is needless to expect an immediate announcement of any final determination as to the prices at which the various properties will enter the combine. North Butte, Butte Coalition, and Superior & Pittsburg have nothing to show in the way of smelter assets, and the companies possessing their own railroads, mills, and smelters must receive proper compensation therefor. The deductions below take consideration of earning power only; the question of property assets is a matter for future adjustment.

The following figures deal with the various producing properties to be embraced in the new company. In all of the companies treated, save the Utah Consolidated, the effort has been to indicate production close to current output. The Utah Consolidated property, however, is producing at the present time about 10,000,000 lb. of copper only, but as it expects soon after the first of the year to have its ore treated at the new smelter of the International Smelting & Refining Co., 16,000,000 lb. has been assumed as the yearly output. This is somewhat below the expectation of the company when the new smelter is in regular operation.

| | Shares. | Production, lb. | Cost, per lb. | Profits on 13c. copper. | Total value per share |
|----------------------|-----------|-----------------|---------------------|-------------------------|-----------------------|
| Amalgamated | 1,538,000 | 205,000,000 | \$0.10 | \$6,150,000 | 93 |
| Anaconda | 1,200,000 | 86,000,000 | 0.10 ¼ | 2,400,000 | 47 ½ |
| North Butte | 400,000 | 40,000,000 | 0.09 | 1,600,000 | 84 ½ |
| Butte Coalition | 1,000,000 | 38,000,000 | 0.10 | 1,140,000 | 25 ½ |
| Utah Consolidated | 300,000 | 16,000,000 | 0.08 | 800,000 | 51 |
| Utah Copper | 725,000 | 60,000,000 | 0.08 | 3,000,000 | 80 |
| Nevada Consolidated | 2,000,000 | 60,000,000 | 0.08 | 3,000,000 | 30 |
| Greene-Cananea | 2,325,000 | 45,000,000 | 0.10 | 1,350,000 | 14 |

Production of Gold and Silver in the United States for the Calendar Year 1908.

The United States Geological Survey and the Bureau of the Mint, acting in co-operation in the examination and analysis of reports from private refineries and records of Federal mints and assay offices, have determined the finished product from domestic mines in 1908 to have been as given below. The unusual delay in furnishing these figures this year has been caused by wholly unlooked-for difficulties in adjusting the data furnished. The product of gold was 4,574,340 fine ounces valued at \$94,560,000, and the production of silver was 52,440,800 fine ounces, with the commercial value (at the average price for the year) of \$28,050,600. As compared with the figures for 1907 the above shows an increase in the gold product of \$4,124,300 and a decrease in the silver product of 4,073,900 fine ounces. Of the 23 States and Territories producing gold, 9 show an increase of production, while 14 show a decrease. Of the 26 States and Territories producing silver, 13 show an increase and 13 a decrease.

| State or Territory. | Gold | | Silver | |
|---------------------|-----------|------------|------------|------------|
| | Fine oz. | Value. | Fine oz. | Com'l val. |
| Alabama | 1,993 | \$ 41,200 | 400 | \$ 200 |
| Alaska | 960,669 | 19,858,800 | 204,600 | 109,400 |
| Arizona | 120,937 | 2,500,000 | 2,900,000 | 1,551,200 |
| California | 935,074 | 19,329,700 | 1,703,700 | 911,200 |
| Colorado | 1,106,385 | 22,871,000 | 10,150,200 | 5,429,400 |
| Georgia | 2,719 | 56,200 | 200 | 100 |
| Idaho | 69,829 | 1,443,500 | 7,558,300 | 4,042,900 |

| Wyoming | 368 | 7,600 | 3,500 | 1,900 |

Total4,574,340 \$94,560,000 52,440,800 \$28,050,600

The commercial value of fine silver in 1908 averaged \$0.5349 per ounce.

Copper Prices.

That copper will go to 16c. by Christmas is generally anticipated in the copper trade, and there is every indication that prices between now and the end of the year will be materially higher. Consumers who were skeptical when the metal was hanging dull at 12¾ to 13c. and refused to buy more than actual requirements for a short period will probably be obliged to pay 1½ to 2c. above what they could have secured the copper for a few weeks ago. The United Metals Selling Co. has been naming 13¾c. for electrolytic brands. Sales of Lake copper at 14c., 30 days, represent the best figure for months. There is a good demand for this brand, and with Calumet & Hecla out of the market there appears a better chance for the smaller producers to get top prices. Middle Western manufacturers who are large consumers of Michigan copper have been anxious buyers recently. When the Metals Selling Co. put its price up to 13½c. it began to book January contracts in large volume, and its current advance to 13¾c. indicates its willingness to consider February business.—Boston News Bureau.

EDITORIAL.

MINING machinery for initial plant on a mining property formerly could be entered free of duty into Mexico. The rebate, however, is no longer allowed except by special concession from the Minister of Fomento. There is no difficulty in obtaining this where the case is genuine and not a mere attempt at evasion of customs duties. The present Minister of Fomento, Mr. Olegario Molina, is a liberal gentleman, zealous in the promotion of the mining interests of the country, equally when controlled by foreigners as when owned by Mexicans.

BUTTE is awakening to a renewed interest in politics. The theatric welcome extended to Mr. F. A. Heinze on his recent visit is said now to have been carefully staged with one eye on the prosecuting attorney in New York and the other on the plain voters of Montana. Just what is up is uncertain, but there are rumors of an effort on Mr. Heinze's part to re-elect Mr. W. A. Clark to the Senate in the place of Mr. T. H. Carter. We hope this does not mean a recurrence of the nasty fighting that so long disgraced the politics and government of that great State.

VICTIMS to carelessness in the handling of explosives multiply. Treacherous powders are practically unknown today. Spontaneous combustion is so rare as to offer a feeble and scarcely credible excuse for accidents. But as Lieutenant Walke dryly remarked, "the function of an explosive is to explode." If men will insist on tamping powder with an iron bar they must expect to strike fire and pay a heavy penalty. The accident in the Keystone mine, Amador county, California, noted in our news department this week, gives emphasis to our comment.

SAN FRANCISCO has decided to celebrate the opening of the Panama Canal in 1915 by a world's fair to be called the Panama-Pacific Exposition. An organization has been effected, and invitations have been extended to foreign countries to participate. The fair will undoubtedly be one of the most notable ever held. Aside from the customary features of such an enterprise, the Spanish note will be strongly sounded. California harks back to Spanish beginnings; her recent celebration of recovery from the disaster of 1906 was made to turn upon a point in history which linked the name of Gaspar de Portolá with San Francisco Bay. The opening of the Panama Canal, which will mark the commencement of a new era for the West Coast States, will occur, it so happens, almost exactly on the fourth centennial of the discovery of the Pacific by Vasco

Nuñez de Balboa. From the summit of the low range of hills on the Isthmus of Panama, September 26, 1513, the great ocean was first seen by the Spanish conquistador, and there was first dreamed the hope of cutting the narrow neck of land which barred the passage to the Indies. In a peculiar way this exposition will call attention also to the days of the Argonauts, and the early glory of Californian gold mining. This will re-awaken interest in the possibilities which remain of creating great mining enterprises along the Mother Lode and northern Gold Belt. There is no other place where so many opportunities for profitable gold mining lie neglected as in the foothills of the Sierra Nevada.

Geology as She Is Wrote.

What a man knows he can explain lucidly. One who is master of a subject can make it clear to the ordinary intelligence, even though the matter be recondite. One kind of knowledge is as difficult as another, and no more so. It is a question of thoroughly comprehending every antecedent fact and circumstance. Those being known the mysteries disappear, and all is as simple as that two and two make four. The example of 'geology as she is wrote' which we quote below carries with it a warning to engineers. It is an example of deficient training in one of the fundamental sciences by the application of which, in part, the mining engineer earns his bread and butter; and it also illustrates the helplessness of a mind untrained in the technique of expression.

"I am free to confess that under normal conditions the appearance and mineralization of the ore shoot on the 7th level, supposing it to be the deepest development at the time of my examination, would offer little encouragement for the future of the mine with deeper development, but in view of Mr. K——'s statement as to the conditions on the 8th level and in view of the great movements which seem to have recurred at various intervals even after the depositions the appearance and mineralization of the ore shoot on the 7th level which is a frequent and to be expected occurrence in any ore deposit, it seems from the number of faults, both longitudinal and transverse, that there have been a number of periods of elevation and subsidence of one or both sides of the fault, so if the present 7th level might have at one time represented the depth to which secondary enrichment reached at one period, or the then ground water level, subsequent elevation of the country may have lowered the water level and thus have extended the secondary enrichment to greater depth, and this may have been done through successive periods and finally the whole may have subsided below the present permanent water level, and thus the future prospects of the mine with depth may be very much extended."

The above is not from a romance written by a quack for a set of wild-cat promoters, but is taken verbatim from a serious report to one of the most prominent companies in the United States by an engineer of wide reputation. The brain grows dizzy in attempting to follow the fearful oscillations, sub-

sidences, and elevations that seem "upsetting the stability of the earth alternately on one and the other side of the numerous faults. The ebb and flow of the ground-waters washing that copper 'reef' must indeed have produced appalling changes. Might not so bewildered an engineer have done quite as well to have stood safely on the apex, singing "what are the wild waves saying?"

Pan-Americanism.

Pan-Americanism, as discussed by Mr. Lee Fraser elsewhere in this issue, calls renewed attention to a growing misconception among Latin-Americans of the attitude of the United States toward expansion. That such a sentiment should be encouraged by commercial rivals is natural. At the present moment the purposes of the Government with regard to Nicaragua are being watched with anxiety. The development of mines in Spanish America is one of the most promising opportunities now lying open to our capitalists, and the good-will of the local governments and of the people counts heavily. That the sentiment against further territorial aggrandizement is dominant in this country is indubitable. It is only when goaded on by the jingoes that a contrary disposition becomes manifest. In fact, even under such stimulus, no absorption of territory has taken place except as an accident of war. The United States embarked upon the Spanish-American war fully pledged not to acquire territory. This was with an eye to Cuba, other possibilities being lost sight of at the moment. With respect to Cuba absolute faith has been kept. A more tender regard for autonomy would be hard to duplicate, for the vested interests of Americans in that island are so great that incentives to annexation were strong. *A de facto* government existed in Cuba, and had proved itself competent to withstand the power of Spain. No such condition obtained in Porto Rico or in the Philippines. Those dependencies fell under American guardianship, and no one can certainly foretell what their ultimate status may become. They were assuredly not annexed with any desire to increase American possessions, and the fact that such a spirit does not animate this country is further evidenced by the recognition of independence on the part of Panama, where, if ever, there was some excuse for assuming control of the territory. Restraint in this particular should redound to our credit as a nation.

It is to be hoped that the United States will not commit the tactical blunder of assuming a protectorate over Nicaragua, nor of attempting joint control with Mexico. Protection of the life and interests of American citizens in the customary way, without vociferation and moral disquisitions, but swiftly and decisively, by force of arms if need be, will promote the development of responsible government in Central America. A country held to accountability as a member of the family of nations is more useful than one which is denied the means of growth through independence. Furthermore, it is well to bear in mind that the foreigner has largely fostered corrupt government in these petty republics. Under an honest administration the granting of monopolies

and princely concessions would cease. The quest of such prizes is the basis for a large amount of the graft prevalent in Central America; it is also the cause of friction, leading to revolutions. These are usually set in motion for the benefit of foreign interests. The answer of President Zelaya to the letter of Secretary Knox, requesting that a commission be sent to investigate affairs in Nicaragua, was a diplomatic move, and the silence at Washington regarding this proposal is significant.

Conservation and Alaskan Coal Lands.

In another column of this issue Mr. Horace V. Winchell calls attention strikingly to some of the complications that have arisen recently as a result of the conservation policy applied to the public lands. Mr. Winchell is evidently finely indignant and quite worked up through sympathy for the poor widow zealously guarding her six trees on the bleak Dakota prairie. We fancy we discover in her at least a family resemblance to that other well known widow whose duty in life it is to come out and cry publicly wherever an attempt is made to regulate the affairs of corporations—but that is aside from the main point; one which Mr. Winchell very properly makes.

There can be no retroactive legislation in the United States, nor can administrative process supersede Statute law. However much we may regret in a particular case that the conservation policy was not sooner adopted or that it has not yet been written into the law, the fact is that the law, as it now stands, must be obeyed. If there are disagreements as to its interpretation or as to the facts of the case, it is for the courts to decide. Any attempts to evade or nullify the law are, at least, as unfortunate when undertaken by Government officers as when by corporations. We heartily subscribe to Mr. Gifford Pinchot's dictum that a public officer should go just as far as the law permits rather than commands, in protecting the public interest; but he should not go farther.

In the cases of the Alaskan coal lands the facts seem to be that the United States coal land laws were extended to that territory in 1904. Numerous claims were promptly taken up under the law. They were at once attacked as fraudulent, and no patents have been allowed. Many such cases are now pending. In the meantime industrial development in the region affected has undoubtedly failed to come as rapidly as was anticipated, and this uncertainty as to title is manifestly one cause. In an attempt to remedy matters Congress passed supplementary legislation designed to allow under the new law, which provided for enlarged claims, patents on land entered "in good faith" under the old statute. Incidentally the new law includes rigid restrictions against consolidation of claims in the interest of monopoly. The coal land claimants have refused to accept the new law, and have preferred, as is clearly their right, to stand on the law as it existed when they took up the land. They have stoutly maintained that their claims were not fraudulently entered. This seems to us properly a case for judicial decision, and whether the poor prospector or the rich Guggenheims

be the real parties in interest, has nothing to do with that fact. We have assurances, which we are bound to respect, to the effect that certain of the most famous claims at least, are not now and never have been owned by the Guggenheims but are in fact, as alleged, the property of the claimants in interest. It is none the less probable that if the claims be confirmed there will be a market for them with the interests now building railroads in the vicinity. At least that has been the universal history in the States. The railroads, for their own protection as well as to stimulate traffic, must and do become heavy owners of coal properties. This entails much incidental hardship as well as benefits. Neither the matter of relations of railroads to coal land, nor questions of monopoly have anything to do, however, with whether the coal land claimants in Alaska are entitled to what they ask. This is a question of law and evidence and should be decided as such. There should be some limit established beyond which the Land Office could not hold up a claim, or the right of mandamus should be given the claimant. The American people cannot afford to be unjust, no matter how worthy the motive.

Qualified Engineers.

Fixing a grade for mining engineers as a license to practice has been frequently discussed in these columns, editorially and by correspondents. The subject was reviewed last week by Mr. John M. Nicol, who sees in the proposed Bureau of Mines a possible means of carrying into effect some scheme for determining who may and who may not exercise the functions of a mining engineer. Mr. Nicol, writing from the political focus of a strongly centralized government, has overlooked the fact of jealously guarded 'States rights' in this country. A plan which might be feasible under the Mexican system would not be possible here. Each State has authority over the licensing of men to perform the duties of any trade or profession. These matters fall under the head of police regulations. The only excuse which could be offered for interfering with the free activities of a man choosing to do mine-engineering work lies in the protection of the lives and property of other people. Such restriction may be set by the State; under no circumstances can this right be arrogated by the Federal Government.

Licenses are granted to physicians and to lawyers, after examination. No question of university degrees arises. The fact to be determined is the fitness of the man for the work he proposes to do. It matters not how he acquired his knowledge. Up to the present time no such restrictions have been imposed upon any of the professions as safeguard the charmed group of doctors and lawyers who have passed their examinations. Any man can be his own physician; he may plead his own cause before judge and jury; but he may not serve another without license. The time will come, no doubt, when mining engineers, together with civil, mechanical, electrical engineers, and architects, will come under the scrutiny of the State, for the protection of both the public and the professions from the evils of unqualified practitioners.

TESTS ON ACID REGENERATION OF CYANIDE SOLUTIONS.

Written for the MINING AND SCIENTIFIC PRESS
By R. P. WHELOCK.

An opportunity was recently presented to make an investigation of the cyanide treatment at a certain plant with the object of decreasing the cyanide consumption. Because of limited time and facilities, exhaustive analyses were impossible, consequently the results obtained are not as conclusive as might be desired. The plant mentioned was designed primarily for the treatment, by leaching, of the coarser portion of a roughly sized accumulation of mill tailing. Though rated at 150 tons daily capacity, it has, under the most favorable conditions, an estimated daily capacity of 145 tons, allowing five days for total treatment. Its chief features are five 150-ton leaching vats (loaded and unloaded with the aid of belt-conveyors), from which the gold-bearing solution flows through one of two small distributing tanks to one or more of four 5-compartment zinc-boxes, thence to the storage-sumps, where it is built up with cyanide as desired and returned to the leaching vats by means of a centrifugal pump.

It has been customary to pass from 300 to 500 tons of solution through each charge during its course of treatment, the amount being governed chiefly by the rate of percolation. Starting with a solution containing 5 lb. of KCy per ton, the strength is gradually decreased to 2 lb. in the succeeding solutions and this, on the last day, is followed by a wash of from 20 to 30 tons of water. A vacuum-pump assists in draining the vat. The tailing discharged contains about 20% moisture. Sodium cyanide is used exclusively, but all cyanide contents are noted in terms of 100% KCy. All titrations for free cyanide during these experiments, were made by Liebig's method, using silver nitrate and potassium iodide for an indicator, and titrations for protective alkali were made with a sulphuric acid solution and phenol phthalein after the addition of silver nitrate. For the sake of later brevity, we will also state that the results of titrations for free cyanide and protective alkalinity are given in pounds of potassium cyanide and calcium hydrate respectively per ton of solution.

At the time these investigations were undertaken, the cyanide consumption had increased to about 5 lb. KCy per ton of ore. Preliminary experiments, while not exhaustive as to the cyanicides present in the ore treated, had demonstrated that copper was the chief one and that its compounds soluble in cyanide solution were probably present in sufficient quantity to account for the loss of cyanide in treatment. After six months' operation of the plant, a number of determinations of the working solutions showed from 0.45 to 0.50% copper. Assays during the succeeding six months, and at the time when these tests were made, gave the same range. An average sample of the tailing being treated showed 0.61% copper. This copper occurs mainly as chrysocolla, malachite, and chalcocite. Lead is also present as galena, cerussite, and wulfenite. Merely to satisfy curiosity, rough tests were made to determine the relative

effects of these minerals upon a cyanide solution. A picked sample of each mineral was taken from the ore-bins and crushed to pass an 80-mesh screen. One hundred grams of each pulp-sample was treated with 250 c.c. of an 8.55-lb. KCy solution for 24 hours in a 300-c.c. bottle. The bottles were frequently shaken. While the manner of preparing the samples precluded the possibility of their being free from foreign cyanicides, yet the results seemed sufficiently marked to make them worthy of passing mention. The copper assays of each sample, and the cyanide titrations of the solutions at the end of 24 hours follow:

| | KCy, lb. | Copper, % |
|-------------------|-------------|--------------|
| Chrysocolla | 0.033 | 35.90 |
| Malachite | Trace | 64.90* |
| Chalcocite | Trace | 44.65 |
| Galena | 2.70 | 1.45 |
| Cerussite | 3.05 | 0.85 |
| Wulfenite | 8.30 | Trace |

*Probably mixed with some chalcocite.

Another sample of 100 gm. of malachite was taken and treated with 250 c.c. of water in which was dissolved 108.14 gm. KCy. After 12 hours, a consumption of 96.89 gm. KCy was indicated. Considerations which it is unnecessary to detail rendered it inexpedient to attempt the removal of the copper before cyanide treatment, and, to me, the most obvious alternative was the precipitation of the copper held in solution, and the liberation of its combined cyanide, if possible. It was known that upon the addition of acid to a cyanide solution containing double cyanides of the heavy metals with the alkali metals, most of the heavy metals are precipitated as cyanides. In the case of copper the reaction is probably,

Julian and Smart, speaking of the dissociation of cyanogen, even by weak acids, state: "If, however, the acid is dilute, * * * the action (of acid upon cyanide) is similar to that which occurs with water, thus,

In very dilute solutions the HCy escapes into the air so slowly that even some hours after the solution became acid practically the whole of the HCy is still present, and if alkali is added it will be found that the solution has lost little of its original strength. Some HCyO and KCyO is also formed in the presence of dissolved air."

With these statements in mind, I first determined the approximate amount of acid required to produce as complete precipitation as possible, using for the purpose 500 c.c. of a representative sample of the cyanide sump-solutions containing 2.2 lb. KCy, 1.5 lb. Ca(OH)₂, and 0.48% Cu. To this was added, 1 c.c. at a time, a 50% solution of sulphuric acid. A heavy white precipitate was produced which settled rapidly, leaving a clear solution. At frequent intervals small filtered portions of the solution were tested with a drop of the dilute acid until 15 c.c. of the acid had been added to the original 500 c.c. of KCy solution, when it was found that no further precipitate was produced. Five cubic centimetres of concentrated sulphuric acid were added

to 250 c.c. of the working cyanide solution, which titrated 1.3 lb. KCy and 0.7 lb. $\text{Ca}(\text{OH})_2$. After allowing a few minutes for the precipitate to settle, 10 gm. CaO were added, and the mixture stirred. The presence of undissolved CaO rendered it impossible to tell whether the original precipitate was re-dissolved, or a further precipitate produced. A titration gave 0.1 lb. KCy and 6.7 lb. $\text{Ca}(\text{OH})_2$, the $\text{Ca}(\text{OH})_2$ titration being of small value, however, on account of the indeterminate amount of lime in suspension. Later tests, in which sodium hydrate solution or lime-water were used instead of solid CaO , showed that the precipitate resulting from the addition of acid was re-dissolved, and a loss of free cyanide was shown in each case, undoubtedly due to the loss of HCy during the manipulation of the acidified solution. A 1000-c.c. sample was taken from the storage sumps. Titrations showed 1.4 lb. KCy and 0.7 lb. $\text{Ca}(\text{OH})_2$. To this were added 15 c.c. concentrated H_2SO_4 , and the solution agitated just sufficiently to secure a homogeneous mixture. This was immediately filtered into a beaker containing 200 c.c. of saturated lime-water. A titration showed 12.5 lb. KCy. Allowing for the increase in volume due to the addition of the lime-water, the result was 15 lb. KCy. A number of experiments on the same scale, using either solid CaO or lime-water, confirmed this result, the titrations varying from 14.9 to 15.3 lb. KCy, after making necessary corrections for dilution.

It now seemed expedient to make a test upon a somewhat larger scale, and for the purpose an empty cyanide case, approximately 21 in. square and 12 in. deep, was secured. In this was placed 160 lb. of the working cyanide solution, containing 1.5 lb. KCy, and 1.5 lb. $\text{Ca}(\text{OH})_2$ per ton, 0.46% copper, and a trace of gold. To this was added 2.5 lb. of commercial sulphuric acid. The usual heavy white precipitate was allowed to settle. Some gas was evolved, making it necessary to stir the top of the solution in order to facilitate the settlement of a portion of the precipitate which entangled gas-bubbles rendered buoyant. Otherwise the precipitate settled rapidly, and the resultant solution was quite clear. After one-half hour, the supernatant liquid was decanted into another cyanide case containing 7 lb. of commercial CaO , which was frequently stirred during the decantation. At the end of another half hour, a sample taken for titration showed 16.3 lb. KCy. After the lapse of three hours, titrations gave 15.6 lb. KCy and 2 lb. $\text{Ca}(\text{OH})_2$.

For the purpose of determining the permanency of the cyanide content, the solution was allowed to stand several days. After 24 hr. the result of a titration was 15.6 lb. KCy, and after 48 hr., 15.7 lb. KCy and 2 lb. $\text{Ca}(\text{OH})_2$. After having stood for 10 days another titration was made, and showed 20 lb. KCy, the increase in value being due to the fact that approximately one-quarter of the solution had evaporated. The precipitate from this test was collected, dried, and weighed, as a check upon the precipitation of the copper. The drying being conducted rather crudely, resulted in the decomposition of a small portion of the precipitate; consequently the assays are of no value for the determination of its

percentage composition, though they serve for the check mentioned. The weight, as dried, was 1 lb., and the assays were, gold, 0.09 oz. per ton; silver, 0.21 oz.; copper, 68.15%. In the original, 160 lb. of solution at 0.46 copper, there was 0.736 lb. of copper. The precipitate at 68.15% contained 0.6815 lb. copper, and the resultant regenerated solution 0.029%, or 0.0464 lb., a total of 0.728 lb. The copper in the regenerated solution was probably due to the re-dissolution of a small portion of the precipitate which passed into the lime receptacle during the process of decantation.

To determine the dissolving power of the regenerated solution, a test was made upon a sample of tailing. Four bell-jars were made to serve as shown in Fig. 1, which illustrates one of the two units of the apparatus employed. *A* is an inverted bell-jar to hold solution, fitted with a glass-tube and stop-cock *B*, which regulates the flow of solution into the bell-jar *C*. The latter contains a canvas bag *D* for holding the pulp under treatment, and to serve as a filter. *E* is a glass-tube and stop-cock for regulating the flow of solution from the jar *C*. *F* is a beaker to catch the solution. The solution collected in this beaker was poured back into jar *A* as desired. Of the tailing, two 5-lb. samples were taken. Lime was mixed with each sample in the proportion of 9 lb. per ton of ore, which was the amount regularly used in the large leaching vats. The samples, No. 1 and 2, were placed in bags *D* and *D'* respectively. Sample No. 1 was treated with a regenerated solution titrating 15.6 lb. KCy, but diluted with water to 5.05 lb, with 0.5 lb. $\text{Ca}(\text{OH})_2$. Sample No. 2 was treated with a portion of the working solution titrating 1.6 lb. KCy, but built up with cyanide to 5 lb., having 1.4 lb. $\text{Ca}(\text{OH})_2$; 2000 c.c. of solution were used in each case. The rate of flow was so regulated that this amount leached through the pulp about once every four hours. The subsequent titrations of samples of the two solutions are given below.

| | Solution No. 1. | | Solution No. 2. | |
|-------------------|-----------------|--------------------------------|-----------------|--------------------------------|
| | KCy, lb. | $\text{Ca}(\text{OH})_2$, lb. | KCy, lb. | $\text{Ca}(\text{OH})_2$, lb. |
| | per ton. | per ton. | per ton. | per ton. |
| At start | 5.05 | 0.50 | 5.00 | 1.40 |
| After 16 hours... | 3.35 | ... | 4.50 | ... |
| After 25 hours... | 2.35 | 0.25 | 3.20 | 0.25 |
| After 40 hours... | 1.70 | 0.20 | 2.25 | 0.20 |
| After 45 hours... | 1.20 | 0.20 | 2.00 | 0.15 |

After 45 hr., the solution was drained off and each sample was treated with 2000 c.c. of wash-water, which titrated KCy and $\text{Ca}(\text{OH})_2$ respectively for solution No. 1, 0.125 and 0.025, and for No. 2, 0.325 and 0.037 lb. per ton.

The gold and copper assays tabulated are as follows:

| Sample. | Before treatment. | | After treatment. | |
|-------------------|-------------------|-----------|------------------|-----------|
| | Gold, oz. | Copper, % | Gold, oz. | Copper, % |
| Heads of test.... | 0.13 | 0.6580 | | |
| Tailing No. 1.... | | | 0.040 | 0.6270 |
| Tailing No. 2.... | | | 0.040 | 0.6420 |
| Solution No. 1... | Trace | 0.0223 | 0.073 | 0.0573 |
| Solution No. 2... | Trace | 0.4640 | 0.057 | 0.4820 |
| Wash No. 1..... | | | 0.020 | |
| Wash No. 2..... | | | 0.026 | |

It was thought that possibly the alkalinity of the

solution used might have some bearing on the extraction and consumption of cyanide, consequently an attempt was made to secure appropriate data. A sample of tailing was secured which assayed 0.246 oz. gold per ton, 0.894 oz. silver, and 0.768% copper. The sample contained 11% moisture, but all assays are based upon the dry weight. Three portions, No. 1, 2, and 3, of 5 lb. each, undried weight, were taken, and to each portion was added 11.34 gm. CaO, equivalent to 10 lb. per ton. Three units of the leaching apparatus described in connection with the previous experiment were used, and samples No. 1, 2, and 3 were placed in jars O, C', and C'', respectively. Three solutions, No. 1, 2, and 3, were prepared.

Solution No. 1 consisted of regenerated cyanide solution at 19.2 lb. KCy. This was diluted to 4.5 lb. KCy, with 0.4 lb. Ca(OH)₂. The alkalinity was reduced by using H₂SO₄. Solution No. 2 was a portion of solution No. 1, diluted, with the alkalinity increased by the addition of CaO. Solution No. 3 was regular stock-solution, titrating 1.5 lb. KCy and 1.1 lb. Ca(OH)₂, built up with KCy and CaO. The final titrations and assays on the three foregoing solutions were:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. | Gold, oz. per ton. | Copper, % |
|------------|----------------------|---------------------------------------|-----------------------|--------------|
| No. 1..... | 4.35 | 0.1 | Trace | 0.0107 |
| No. 2..... | 4.55 | 4.0 | Trace | 0.0107 |
| No. 3..... | 4.85 | 1.9 | 0.016 | 0.3280 |

Samples No. 1, 2, and 3 were treated with 2000 c.c. each of solutions No. 1, 2, and 3, respectively, as in the previous test. The record of titrations and assays is as follows. After 4 hr., the solutions having leached through the pulp once:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. |
|------------|----------------------|---------------------------------------|
| No. 1..... | 2.00 | 1.0 |
| No. 2..... | 2.90 | 1.3 |
| No. 3..... | 3.85 | 1.9 |

After 17 hr., the solution having leached through twice:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. |
|------------|----------------------|---------------------------------------|
| No. 1..... | 1.3 | 1.0 |
| No. 2..... | 1.6 | 0.7 |
| No. 3..... | 2.6 | 1.3 |

At this point 1¼ lb. of the pulp was taken from each jar for assay, and a sample was also taken from each solution, sufficient to preserve the original ratio between the pulp and solution. The assays were as follows.

| | Pulp | | | Solution | |
|-----------|--------------|----------------|--------------|--------------|--------------|
| | Gold, oz. | Silver, oz. | Copper, % | Gold, oz. | Copper, % |
| No. 1.... | 0.130 | 0.710 | 0.689 | 0.143 | 0.0555 |
| No. 2.... | 0.100 | 0.720 | 0.627 | 0.133 | 0.0588 |
| No. 3.... | 0.135 | 0.785 | 0.627 | 0.093 | 0.3478 |

The treatment was continued with the remainder

of the pulp solution. After 24 hr., the solution having leached through three times, the titrations were as follows:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. |
|------------|----------------------|---------------------------------------|
| No. 1..... | 1.0 | 0.90 |
| No. 2..... | 1.5 | 0.75 |
| No. 3..... | 2.2 | 1.30 |

After 41 hr., the solution having leached through four times:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. |
|------------|----------------------|---------------------------------------|
| No. 1..... | 0.60 | 1.00 |
| No. 3..... | 1.25 | 0.75 |
| No. 2..... | 1.55 | 1.20 |

Solution assays at this point were:

| | Gold, oz. | Copper, % |
|------------|--------------|--------------|
| No. 1..... | 0.223 | 0.0630 |
| No. 2..... | 0.153 | 0.0672 |
| No. 3..... | 0.123 | 0.3783 |

The solution was drawn off and the pulp allowed to drain. Each sample was then washed with 1500 c.c. of water. Titrations and assays of wash-water were:

| | KCy, lb. per ton. | Ca(OH) ₂ , lb. per ton. | Gold, oz. |
|------------|----------------------|---------------------------------------|--------------|
| No. 1..... | 0.20 | 0.70 | 0.070 |
| No. 2..... | 0.25 | 0.25 | 0.063 |
| No. 3..... | 0.45 | 0.45 | 0.053 |

The assays of the pulp tailing of this test were:

| | Gold, oz. | Silver, oz. | Copper, % |
|------------|--------------|----------------|--------------|
| No. 1..... | 0.120 | 0.700 | 0.611 |
| No. 2..... | 0.115 | 0.685 | 0.595 |
| No. 3..... | 0.150 | 0.780 | 0.689 |

It was now decided to make a regeneration test upon a scale more nearly approaching that which would be required for the practical application of the method; consequently two tanks were arranged as shown in Fig. 2. Tank A had 17 tons capacity, and tank E 25. Three successive charges of solution were treated. For the first, 7.63 tons of old KCy solution was pumped into tank A at 1.9 lb. KCy, into 1.45 lb. Ca(OH)₂, assaying 0.02 oz. gold and

Fig. 2.

0.48% copper. Into this was stirred 202 lb. of commercial sulphuric acid. After the addition of the acid, two hours were allowed for the settlement of the precipitate, the top of the solution being stirred occasionally to facilitate the settling process. The solution was then decanted by means of the float-valve B through the box D into tank E. Lime was added to box D from time to time until the amount so added aggregated 190 lb. A titration of the re-

generated solution showed 8 lb. KCy and 0.75 lb. Ca(OH)_2 . It was found difficult to keep the decanted solution alkaline, the frequent addition of fresh lime to box *D*, and constant stirring, being necessary. A small sample taken from tank *A* before decantation, and made alkaline, gave 15.6 lb. KCy. A disagreeable odor was given off during the action of the acid on the cyanide solution, and the odor of HCy seemed to be distinguishable. The escaping gas had a tendency to produce headache. It was thought that considerable of the HCy must have escaped during decantation on account of the difference between the strength of the final regenerated solution (8 lb. KCy) and the strength obtained from the small test-sample (15.6 lb. KCy); consequently, for the second charge, the piping was changed slightly, a third tank was added, and a centrifugal pump was connected to the system as

Fig. 3.

shown in the diagram, Fig. 3; 16 tons of old solution, titrating 1.65 lb. KCy and 1.65 lb. Ca(OH)_2 , and assaying 0.033 oz. gold and 0.48% copper was pumped into tank *A*. To this was added 498 lb. of commercial sulphuric acid. A small sample was taken after the addition of the acid. This was made alkaline with lime and titrated 15.8 lb. KCy. While the precipitate was settling, lime was added to the barrel *D*, and by means of the centrifugal pump the solution in the tank *E*, from the previous charge, was circulated through the barrel *D* until it was thoroughly saturated with lime. The solution from tank *A* was decanted into tank *E*. It will be noted that the discharge pipe from *A* was extended below the surface of the solution in *E* to prevent, so far as possible, the aeration of the acidified solution. During the decantation, water was run through the barrel *D*, to which lime was continually added. A total of 8½ tons of water, and 325 lb. of lime was used. As tank *E* became full, part of the solution was allowed to flow into tank *K*. The final product from the two charges was 13 tons at 9.2 lb. KCy in tank *K*, 16 tons at 7 lb. KCy in tank *E*, and 3 tons not decanted from tank *A*.

| | |
|--|----------|
| | KCy, lb. |
| 13 tons at 9.2 lb. KCy..... | 119.60 |
| 16 tons at 7.0 lb. KCy..... | 112.00 |
| | 231.60 |
| Less first charge, 7.63 tons at 8.0 lb. KCy..... | 61.04 |
| 13 tons from second charge..... | 170.56 |

This equals 13.12 lb. KCy per ton treated. After about 16 hr., the balance of the solution in tank *A* was decanted into a solution of lime and a titration

gave only 2.5 lb. KCy, after allowance had been made for the dilution. There had evidently been a considerable evolution of HCy from the acidified solution.

For the third charge, the arrangement of the apparatus used was the same as for the second charge. However, about three tons of the regenerated solution from the first two charges was left in tank *E*. Into this two tons of water was passed through barrel *D*, to which lime had been added. The result was five tons of a strong lime solution which titrated 6 lb. KCy. Fifteen tons of old cyanide solution titrating 1.65 lb. KCy and 1.65 lb. Ca(OH)_2 was pumped into tank *A*. This was treated with 418 lb. of commercial sulphuric acid. After settlement of the precipitate, 12 tons of the acidified solution was decanted into tank *E*. During the decantation, the solution in tank *E* was circulated through barrel *D*, into which fresh lime was frequently placed. The amount of lime added to this charge was 455 lb. A titration of the resultant solution gave 12.2 lb. KCy. Accounting for the dilution by the five tons at 6 lb. KCy, the 12 tons decanted from the acid tank, if undiluted, should have titrated 14.8 lb. KCy. It was now deemed advisable to test the dissolving power of the regenerated solution upon a working scale. One hundred and forty-five tons of tailing was charged into one of the regular leaching vats. The assay was 0.225 oz. gold per ton. During the charging, lime was mixed with the pulp to the amount of 9 lb. per ton.

There follows a record of the treatment of the tank for three days: First day, 9:45 a.m., pumped on 11 tons solution with 7 lb. KCy per ton, and 11 tons at 9.8 lb. KCy. In this solution I failed to secure the proper neutralization with the lime, consequently, after the addition of sufficient silver nitrate to combine with the free cyanide present, the solution did not show an alkaline reaction with phenol phthalein.

At 4:45 p.m., pumped on 10 tons of 9.8 lb. KCy and 12 tons of 11.7 lb. KCy solution; both of these had 0.2 lb. Ca(OH)_2 . The solution was allowed to stand in contact with the pulp until 7 a.m. of the next day. On the second day, 7 a.m., started leaching at the rate of about two tons per hour. The solution was allowed to flow through one 5-compartment zinc-box into a storage sump. The titrations and assays of samples taken at different times during the day are as follows:

| | | KCy, | Ca(OH)_2 , | Gold, | Copper, |
|------|----------------|--------------|---------------------|-------|---------|
| | | lb. per ton. | lb. per ton. | oz. | % |
| Vat | 7:30 a.m..... | 0.2 | 1.3 | 0.17 | 0.1440 |
| | 9:30 a.m..... | 0.3 | ... | | |
| | 10:30 a.m..... | Trace | 1.2 | 0.21 | 0.1442 |
| | 1:30 p.m..... | 0.05 | 1.5 | 0.21 | 0.1485 |
| | 4:30 p.m..... | 0.05 | 1.5 | 0.20 | 0.1461 |
| Sump | 7:30 a.m..... | ... | ... | 0.003 | |
| | 4:30 p.m..... | ... | ... | 0.007 | |

A boring sample of the vat, taken at 3:30 p.m., gave: sample unwashed, 0.11 oz. gold; sample washed with three charges of water, 0.09 oz. gold. A sample of the solution taken at 1:30 p.m. was regenerated in the laboratory with sulphuric acid and lime, and gave 4.4 lb. KCy. An assay of this regenerated solution showed a trace of gold, and 0.0047% copper.

Lack of sulphuric acid prevented the further treatment of this vat with regenerated solution; consequently at 4:30 p.m., 17 tons of solution from the storage sump, consisting of the solution previously used, and sufficient unused regenerated solution to give a strength of 3.3 lb. KCy and 1.6 lb. Ca(OH)₂ were pumped on the vat. This was allowed to leach slowly all night. At 7:30 the following morning the solution draining from the vat showed 0.05 lb. KCy and 1.8 lb. Ca(OH)₂, 0.25 oz. gold, and 0.2069% copper.

In an attempt to verify the suspicion that the HCy was rapidly lost upon exposure of the acidified solution, the following table was constructed:

| 1 | 2 | 3 | 4 | 5 | 6 |
|--------------|-----------|-----------------------------------|------------------------|---------------------------|-----------------------|
| Acid. | Alkali. | After standing 12 hours. | | | |
| | | Immediate titration, lb. per ton. | Filtered, lb. per ton. | Un-filtered, lb. per ton. | On acid, lb. per ton. |
| Nitric | Lime | 9.2 | 20.5 | 18.5 | 0.3 |
| | NaOH ... | 17.7 | 17.7 | 18.3 | 0.3 |
| Hydrochloric | Lime | 17.5 | ... | 19.8 | 3.6 |
| | NaOH ... | 18.4 | 19.4 | 19.9 | 3.4 |
| Sulphuric | Lime | 15.6 | 17.6 | 16.2 | 0.5 |
| | NaOH ... | 13.3 | 14.6 | 16.2 | 0.5 |

Nitric, hydrochloric, and sulphuric acid was each used in turn as a precipitant, and with the acid, CaO and NaOH were employed to render the acidified solution alkaline, the acidified solution being allowed to filter into a beaker containing 50 gm. CaO or 5 gm. NaOH. The figures in the table represent KCy expressed in pounds per ton of solution. Column 1 shows the acid used. In each case 200 c.c. cyanide solution was treated with 5 c.c. acid. Column 2 shows the alkali used. Column 3 the acid precipitate, immediately filtered off with the least possible manipulation and agitation, the filtrate made alkaline, again filtered, and the second filtrate titrated. Column 4, the acid precipitate, immediately filtered off, the filtrate rendered alkaline, and after being filtered again allowed to stand 12 hr. before being titrated. Column 5, the acid precipitate, filtered off immediately and the filtrate rendered alkaline; the alkaline solution allowed to stand without a second filtering for 12 hr., and then filtered and titrated. Column 6, the unfiltered acidified solution, allowed to stand 12 hr. before the addition of the alkali, then rendered alkaline, filtered, and titrated.

Several tests were made with the precipitate obtained from the acid treatment, substantially as follows: the apparatus used was arranged as shown in Fig. 4. Twenty-five grams of the dried precipitate was placed in flask A. To this was added 50 c.c. water and 50 c.c. concentrated HCl. A cork was placed in the flask with tubing B leading to beaker C. In beaker C was placed 250 c.c. water in which was dissolved 10 gm. NaOH. The content of flask A was then heated to boiling. Titrations of the NaOH solution in beaker C were as shown in the table following.

Fig. 4.

| | KCy, lb. per ton. |
|-------------------|-------------------|
| At start | ... |
| After ½ hour..... | 5.70 |
| After 1 hour..... | 78.75 |

The beaker was then removed, and after standing for 18 hr. a titration gave 79 lb. KCy.

In the foregoing notes, while copper, on account of its predominance, has been considered to the exclusion of other base metals, it is appreciated that there are others present in the solutions treated, notably zinc and lead. If the reactions in the case of copper are

for every pound of copper present there should be recovered 1.03 lb. KCy, consequently for a solution containing 0.5% copper, or 10 lb. per ton, there should be a recovery of 10.3 lb. Titrations of the regenerated solutions, however, frequently showed between 14 and 15 lb. in excess of the strength before treatment, during which it is probable that there were some losses. If one attempt to check the data given, there will be noticed a number of discrepancies, which probably are largely chargeable to experimental error, due to the crudity of the methods and apparatus employed and to failure to appreciate fully all the conditions governing the phenomena observed; yet the results seem to be sufficiently marked, and those of similar tests sufficiently in accord, to justify the conclusion that the process is feasible, and under proper conditions might be commercially profitable. Upon this point, criticism by those interested is desired.

Considering the last of the three tests with the apparatus shown in Fig. 3, the 15 tons of solution treated titrated originally 1.65 lb. KCy, and subsequently (with correction for dilution) 14.8 lb., a net gain of 12.15 per ton, amounting to 182.25 lb. of potassium cyanide, or 143.5 lb. of 127% sodium cyanide for the 15 tons. At 26c. per pound, this would be worth \$37.31. To recover this amount of cyanide, there was used 418 lb. of sulphuric acid at 3.5c. and 455 lb. of lime at 0.6c., a total of \$17.36. These figures show a profit of \$19.95, with no allowance for labor. As the whole operation required the services of but one attendant for a portion of a 3-hr. period, the labor cost was nominal. I also believe that the amount of acid and lime might have been reduced. In addition, there is the precipitate containing cuprous cyanide and probably cyanides of the other metals present in the solution. If the reactions given for copper, and similar reactions for the other cyanides hold good, the precipitate should contain an amount of cyanogen equal to that already released. It is possible to recover a large portion of this, at least, as shown by the last experiment described, though to determine the commercial practicability of the operation would require further investigation. The solutions best adapted to acid regeneration are those low in free cyanide and alkalinity, the precipitation of the dissolved metals as cyanides not commencing until after sufficient acid has been added to neutralize the solution.

CONSERVATION AND SOME DIFFICULTIES.

Written for the MINING AND SCIENTIFIC PRESS
By HORACE V. WINCHELL.

That the industrial development of the United States is one of the marvels of history is a boast of which we Americans are peculiarly proud. Other countries have progressed rapidly in all that makes for national greatness. Commerce has grown wonderfully in all quarters of the globe. The wealth of nations, as of individuals, has been accumulated with unexpected and most surprising rapidity. But in no other place has the rate of increase been so great and the aggregate result of prosperity, industry, and invention so astonishing, as in our own most fertile and richly endowed land. That we owe our position among the foremost nations of the world to the unprecedented liberality of our Government in the disposition of its agricultural and mineral lands for the benefit of all the people and the enrichment of the individual, is a proposition that will hardly be disputed.

Free homes for all who seek them, low-priced mineral, timber, stone, water power, and wealth of every description have been provided to all the world who chose to adopt our country as their own. Indeed, for many years it was our policy to seek immigrants and tempt them with offers of these attractions; the provisions of our laws amounted to an invitation to the settler and prospector to come hither and locate, to make discoveries of mines under the definite promise that they should receive patents therefor. There may be grave difference of opinion as to the advisability of such unrestricted gifts of our natural resources in perpetuity for the asking or mere discovery or improvement; but it was done, and the laws under which it was done are still in almost unmodified force and effect on our statute books; and it is certain that to this policy we owe in large part our leadership among nations today.

Recognizing the fact that our farms, lands, and coalfields are not unlimited, and mindful of the future, a step was taken by Mr. Roosevelt toward arousing public sentiment to such an extent that the laws might be changed and what remains in the possession of the general government reserved or sold under some arrangement which would prevent harmful monopolies and unrestricted corporation control. This movement, which should have been inaugurated years ago, was received with enthusiasm by the people, and pushed along so rapidly that the vehicle was soon ahead of the motive power. The more zealous of our public officials have been proceeding on the assumption that the proposed amendments to the law were already in effect. Such unauthorized action has already created serious trouble and will, unless discontinued, be followed by grave consequences.

The laws at present in force provide for the location of mining claims, for the taking of homesteads, for the sale of coal lands, at a certain price per acre, as has been the custom for many years past. Settlement is thus actually invited and title promised. But the practice is vastly different. If, for example, a poor widow takes up a homestead in North Dakota in ac-

cordance with the law she is at once termed a 'land-grabber', and is subjected to as much expense and indignity as though she were a thief. If there are half a dozen trees on her claim, there is an investigation by several special agents who report that she is endeavoring to procure a timber claim by homestead entry; and effort is made to still further embarrass her by the establishment of a forest reserve or the withdrawal of the land under the pretext that it may be at some time included in some tract that will be overflowed by some water-power scheme or within the limits of some irrigation project, all with entire disregard of the fact that she made her locations under the law prior to the establishment of any such reservations by the Government. If a prospector goes out year after year with his pack animal and outfit and finally fixes on a likely location he is at once branded as a suspect and would-be land-grabber. Emissaries of the forestry bureau 'geologists' of the land department and other \$80 per month employees of unknown (and unsuspected) accomplishments make it their business to see that the poor prospector is put to so much expense and trouble that he is either dead or 'busted' long before he gets the patent promised him by the very same government whose officious agents are now unlawfully opposing him. It is an actual fact that the Anaconda claim in Butte, which has produced untold millions of money in copper, gold, and silver, could not be patented under the rules and regulations now in force without a shaft several hundred feet in depth. Such expensive work is seldom within the resources of a prospector.

If a still more adventurous prospector goes into the unbroken wilderness of Alaska to make mining or coal locations he is either turned down with the statement that it does not matter what the laws are, his location cannot be accepted; or if he finally does get his filing on record he is then falsely placarded from one end of the country to the other as a tool of the iniquitous Guggenheims who are trying to take Alaska away from our dear Uncle Samuel. The charges that are then made against him may be as follows:

1. He is trying to secure by unlawful combination (probably because he has neighbors and is acquainted with them) coal land of incredible value.
2. The land is more valuable for timber than for coal.
3. There may be coal on it; but he has done nothing to prove it, beyond cutting a few miles of trails through the underbrush and digging a few test-pits on the outcrops.
4. In fact it is extremely doubtful whether there is any coal there whatever; and the Government in its wisdom and care for its subjects will protect them from the losses which they would suffer if they attempted to develop a coal mine where there is none. (Of course the Government does not offer to reimburse the prospector for the money he spent on the property, nor is it worth while to remember the few thousands of dollars which he paid into the treasury of the land department for his land at the price fixed by Congress for coal land in Alaska. That will be needed to pay the expenses of other

inspectors when they go up there to contest his neighbors.)

It is a significant fact that although there has been on the United States statute books for more than five years (since April 28, 1904) a law providing for the sale and patenting of coal lands in Alaska, yet there has not up to the present time been one single claim patented. The development of Alaska is not alone retarded; but the industries of the entire Pacific Coast have been asking for cheaper and better coal, which can come from no other place than Alaska. The Navy of the United States is and has been paying a high price for inferior coal on the Pacific; and the Geological Survey has repeatedly recommended the opening of Alaskan coal mines.

With the policy of conservation I am thoroughly and heartily in accord. That the natural wealth of our country should be so used as to last the longest and serve the greatest number, and that title to those natural resources which are everlasting should not be permanently surrendered to private ownership is only a statement of principle which has found expression on the statute books of most nations. But do not let us wrong ourselves and those who have already in good faith acquired rights based upon the laws in existence by upholding violations of those very laws. Having been reared in a land where respect for the law is in-bred let us not withhold our condemnation of those who seek to bring about reforms by premature distortion and over-riding of its plain provisions.

In the Hostotipaquillo district, State of Jalisco, Mexico, the greater part of the ores are found in quartz and contain silver in the form of sulphides, bromides, metallic silver and chlorides, gold, lead, iron (in various forms), and manganese, and in some cases traces of copper. The grade of these ores varies from 400 gm. to 50 kg. of silver per metric ton, some of them containing 3 gm. gold per kilogram of silver, little free-gold being found, as it is usually alloyed with the silver. The treatment of 1000 tons of ore, extracted from various mines, produced on the average \$4 in gold per ton. On trustworthy data one may count upon 2 to 4 gm. of gold per ton of ore, as the average product of all the mines. Up to the present time it has not been considered profitable to treat ores of lower grade than 1 kilo per ton and there are great bodies of ore that have not been touched, which yield from 400 to 600 grams.—*Mexican Mining Journal*.

A delicate qualitative test for zinc is described by Del Campo as follows: Add to an ammoniacal solution containing Zn, 1 c.c. of a 0.5% ether solution of resorcinol. A deep blue coloration develops at the line between the two layers of liquid, either immediately, or in a few minutes. If the proportion of Zn is small (0.005 milligram per cubic centimetre) it will not be perceptible before an hour has elapsed. Cd salts show a green color under these conditions. Cu salts give a black precipitate. In presence of Cu the test may be made for Zn by previously decolorizing by dilute KCy, of which no more than is absolutely necessary must be used.

BANNOCK, NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By CHARLES S. THOMAS.

Bannock is situated in Lander county, Nevada, about 14 miles southwest of Battle Mountain on the main line of the Southern Pacific railroad. Attention was attracted to it in August by discovery of unusually rich free gold in quartz by Alexander Walker, formerly of Cripple Creek, Colorado. Systematic prospecting had been going on in this vicinity in a quiet fashion for some time, but the discovery of the rich gold-bearing quartz apparently in an ore-shoot of some size, together with the prompt sale of the property to responsible Omaha investors, led to a rush to the district. The rich gold ore which was then discovered on the properties of the Nevada-Omaha Mining & Milling Co. occurs as quartz in, or along the walls of, a dike, very probably diabase, intrusive through altered rhyolite porphyry, carrying free gold. Free gold also is present here in the felsitic rock, though the occasional presence of crystal-line quartz may be noted.

In the accompanying figure, (2), I have designated these diabase dikes by the letter 'D'. The one at the extreme right of the picture is near the point where the discovery of gold was made. This figure, by the way, is explanatory of the geology of this district: AA shows the overlying basaltic rocks, 50 to 100 ft. in thickness and locally known as 'Malapai' or 'Malpais'. Underlying this is an altered rhyolite, BB, possibly intermixed with andesite or dacite. It is of unknown thickness and through it the later vein structure gave rise to a re-silicification of the fissure walls, forming what appears to be highly silicified or metamorphosed dikes, CC. There is also, a still further evidence of dike action in intrusive diabase (?), DD, along the fractures and walls of which the straight silicious and felsitic gold ores occur. The veins, CC, are composed of 'honeycombed' quartz, the interstices of which are filled with limonite pseudomorphic after pyrite, and containing gold and silver, principally the former, in varying amount. As far as developments have gone the ore rarely exceeds \$100 per ton in value. The 'Buzzard' mine, situated about two miles north by northwest of Bannock, is, I am informed on good authority, developing one of these oxidized veins and has been continuously mining and marketing ore of an average value of \$75 per ton for more than a year. Pannings made from the Old Iron mine, now embraced in the properties of the Nevada-Omaha Mining & Milling Co., and about 800 ft. north by northeast of the gold discovery above mentioned would fully bear out what is claimed for the Buzzard mine. The two are oxidized veins identical in character. These veins are well defined, within and along the silicified dikes (see Fig. 3), and traceable for miles, while the clear-cut walls speak volumes for their being the fillings of pre-existing true fissures. The diabase (?) dikes were intruded unquestionably subsequent to the surrounding country. Being eruptive they came from the deep-seated interior of the earth. They could not moreover have been subsequent to the vein quartz found in and along their walls.

DEVELOPMENT AT THE ESPERANZA MINE, EL ORO, MEXICO.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. HINDRY.

This famous mine from the date of its discovery up to January 1, 1908, had produced 1,034,662 metric tons having a gross value of ₧44,929,730 at a profit of ₧23,369,316. It is situated in the District of El Oro de Hidalgo, State of Mexico, Mexico, and is connected by a branch narrow-gauge railway with the Mexican National railway lines at Tultenango. It was denounced early in 1890 by August Sahlberg and was put on a paying basis by him. The mine is developed principally along the great San Rafael vein. This marks a fault-fissure which has proved productive through the El Oro, Esperanza, and Mexico mines.

In the development of the vein, drifts were driven along the foot-wall and at times along the hanging-wall. It was early discovered that it paid to keep them in the quartz of the vein, as although this was much harder than the wall-rock, drifts in this latter required heavy timbering and constant repairs because of the swelling of the shales upon exposure to the air. On the other hand, drifts in the quartz of the vein were much less subject to troubles of this nature. In the south section of the mine, the ore-bodies were found chiefly along the hanging wall side of the vein and in order to develop them, cross-cuts were driven through the vein every 15 metres and raises put up from level to level on the foot-wall side of the ore zone. These raises were of two compartments, 4 by 4 ft. in the clear, timbered with 8 by 8 in. timber. One compartment was lined with 2-in. plank for a chute and the other equipped with ladders for a manway. In the north section of the mine a similar proceeding was followed except that the interval between the cross-cuts was increased to 20 m., and, owing to the tendency to crush, the chutes and raises were timbered with solid cribbing 8 by 8 in., this being built in two sections in order that one compartment might be repaired while the other was in service.

Where timber was required in drifts and cross-cuts a standard drift set was used which was made of 10 by 10 in. timber for the posts and cap and a 6 by 10 in. sill. The sets were 7 ft. high in the clear and 5 ft. wide at the bottom by 4 ft. 5 in. wide at the top. They were usually spaced 5 ft. apart, centre to centre, but where the ground was heavy this was reduced to 2 ft. 6 in. and in the case of excessively heavy ground, sets made of 12 by 12 in. and 14 by 14 in. timber were used.

Soft running ground was found at various points on every level in the mine, more especially in regions adjacent to the main fault. This material had more or less the consistence of mush, due to the character of the ground and the water contained. In driving through this character of material, top and side lagging were driven under a 'bridge' on the main set, and breast-boards were used in the face, and as there was considerable of this sort of work to do, which was both slow and expensive, a regular system was devised and men trained to carry it out

were kept at this kind of work exclusively. The scheme as worked out, operated excellently. After its adoption, running ground did not interfere with good progress, as formerly. The system was quite simple and is briefly as follows:

The first procedure was to go back a short distance in the drift and put in two or three standard sets, wedging and blocking them very firmly and putting in 4 by 6 in. 'sprags' or collar braces at top and bottom. The set next to the difficult ground carried a 'bridge' of 6 by 10 in. timber on the cap with sufficient space between it and the cap to permit of the passage of the lagging to be driven, which as a rule, consisted of 4 by 6 in. timber 10 or 12 ft. long, according to the spacing of the sets. This lagging passed over the cap of the forward set and under that of the next set to the rear. The sets in this class of ground were usually spaced as close as the driving of the lagging would permit when this had

Fig. 1. Face of Drift Showing Details of Timbering.

the proper angle. As advance was made into the difficult ground, 'bridges' were placed on the posts as well as the cap and side lagging driven. The usual method of driving the lagging was by means of a ram made of an 8 by 8 in. timber, 10 ft. long, swung by a rope from the cap or lagging of one of the rear sets and capable of delivering a heavy blow when operated by two or three men.

Breast-boards were carried on the front set and these were advanced one at a time, commencing with the top, by means of jack-screws, usually a 'single-jack' machine-drill column or shaft bar, two of these being used, one on each end of the board, the rear or screw ends being supported against a timber placed across from post to post of one of the rear sets, or two timbers placed vertically. The lagging was always kept driven ahead of the breast-boards and these were advanced by means of the pressure of the jack-screws, the mushy wet material being removed from behind the board as it advanced, by hand or a small tool. Sometimes this was not necessary and in fact, precautions had to be taken to prevent a

'run' of the material even through a very small hole. After the top breast-board had been advanced a short distance (6 to 12 in. according to the nature of the ground), it was blocked in position. The pressure from the jack-screws was then transferred to the next board immediately below and this advanced to a point even with the first one and blocked as before. This process was continued until the bottom was reached, after which another start was made on the top board which was again advanced in the same manner as at first, the short blocking at the ends being removed and a longer piece substituted. This process was continued until the breast-boards had been advanced sufficiently to permit of the placing of a new set. Two pieces of timber were now placed upright against the breast-boards, leaving sufficient space between these timbers and the ends of the boards to permit of the placing of the posts of the set. The jack-screws were now transferred to the two upright timbers and a heavy pressure brought to bear on them, the result being that the breast-boards were held solidly in place by the jack-screws. The blocking which had previously been inserted at each end of the breast-boards could now be knocked out and a new drift-set placed. After blocking and wedging this the projecting rear ends of the lagging were cut away close to the cap of the next rear set. This usually resulted in the points of the lagging dropping down on the bridge of the new set just placed. The operation was repeated until the necessity no longer existed.

Sometimes, instead of allowing the lagging to project back of the second set from the breast, a 'tail-piece' was used to keep the points of the lagging at the proper angle for driving. With this method shorter lagging can be used and there will not be so much waste of timber when the rear ends of the lagging are cut away, but this saving is a doubtful economy. When once the idea of the foregoing scheme is grasped, it seems simple enough, but putting it in practice is another matter and takes considerable time and experience. Usually the beginner does not get his lagging started 'square' with the set and in the direction he wants to go. He may also get the lagging started so that in driving, some adjacent pieces cross one another or separate, which is equally bad. He also has trouble when one of the pieces of lagging strikes a hard boulder or rock in the soft material, and the proper handling of the 'battering ram' in advancing the lagging is quite a trick in itself. The blows must be delivered at the proper point, in the proper direction, and with the right intensity; otherwise there will be trouble and nothing is worse to handle than a mass of mud, water, and badly placed timber left by some novice after the failure of his attempt to get through difficult ground. The scheme as outlined is simply an adaptation of the old method of 'fore-poling', the chief innovation being the use of jack-screws for advancing the breast-boards.

The development and blocking out of the San Rafael vein revealed the fact that the orebodies of the south section were smaller in depth both in width and length. The value of the ore also decreased so that in this portion of the mine the pay-

able ore ceased at a point slightly above the fifth level. No further pay rock was found with the exception of a small body of comparatively rich ore found on the seventh level on the foot-wall of the vein. This body was not of any great extent, being roughly lenticular in shape. The ore carried considerable pyrite and the gold and silver were apparently associated with this mineral, as when the pyrite failed to put in an appearance they decreased correspondingly. Explorations in all directions failed to reveal any continuance of this orebody.

The orebodies in the north section of the mine were supposed to be down-thrown portions of the great main orebody which existed before the faulting and scoring away of the upper portion of the vein. As, geologically speaking, as the north section of the

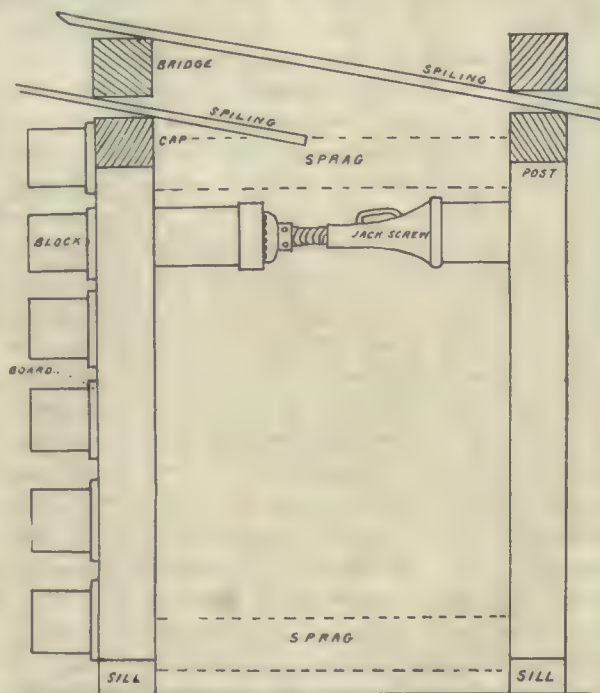

Fig. 2. Arrangement of Jack-Screws and Lagging in Soft Ground.

mine is on a much higher level than the south section, it is quite natural that the payable ore should continue below the horizontal plane where it ceases in the south section. As a matter of fact, this is the case and payable ore is found much below the known limit in the south section of the mine.

The policy of a thorough prospecting of the ground embraced by the boundary lines of the property has always obtained, and with this end in view, numerous cross-cuts were driven into the hanging and foot-walls of the San Rafael vein, some of these extending to the boundary lines. This work was usually done at such times and points that the waste material would be available for filling stopes, by which means the cost of hoisting it to the surface was avoided and what otherwise would be 'dead work' was made to serve a useful purpose in addition to the prospecting of the ground.

Cross-cut No. 14 west on the level No. 4, in the south section of the mine, was started to open the ground adjacent to this point and incidentally to furnish waste material for filling the stopes below on the hanging wall side of the San Rafael vein. In driving this cross-cut two veins were passed through, one of which gave fair assay returns and the other

scarcely any. Driving was started on the vein showing the best ore and the vein widened as progress was made toward the south and the gold and silver contents increased. It was evident that the possibilities of opening a new and hitherto unknown orebody were good. A diamond-drill was immediately put to work on the fifth level, boring a hole horizontally to the west from the end of cross-cut No. 13 west. This hole indicated that the vein at this point was some 22 ft. in width with an average content of 33 grams gold per metric ton. No time was lost in following up the drill-hole with a cross-cut, which, when it penetrated the vein, or rather veins, showed that in place of one there were two. One of these was some 10 ft. in width and contained an average of 100 grams gold per metric ton, while the other was a matter of 6 ft. in width and contained practically no gold or silver. The two veins were separated by 6 ft. of slate strongly impregnated with quartz, and this was the reason that the drill-hole indicated a single wide vein. In the meantime cross-cut No. 13 west had been started on the third level, where the two veins were also found. After opening the veins in the various cross-cuts driven for this purpose, drifts were started north and south along the payable vein (west vein No. 1) and at intervals of 50 ft., raises were put up from level to level. Finally, these veins were developed on the first, second, third, fourth, fifth, sixth, and seventh levels, and the limits of the payable ores sharply defined. It was found that west vein No. 1 was in all cases the one which carried payable ore, No. 2 vein being practically barren except in one place where there appears to have been a slight secondary deposition of gold and silver, presumably derived from No. 1 vein. The No. 1 vein had an inclination or dip to the west while the No. 2 vein dipped to the east, the No. 1 vein being faulted by the No. 2 and other minor veins and slips which, from first to last were the cause of a considerable amount of worry and much calculation in the way of platting of sections, and construction of glass models, before their vagaries as to the direction and amount of displacements were made clear.

The greatest displacement took place at the intersection of the No. 1 and No. 2 veins, the intersection line having, in the main, a horizontal direction. The displacement varied from a few feet up to approximately 50 at the greatest point. The fault is a normal one, the hanging wall having gone down. The minor faults above mentioned varied in throw from a few inches to several feet and their angle and dip appeared to be confined to no particular direction.

Vein No. 1 appeared to be the stronger and more persistent of the two and contained payable ore throughout nearly its entire mass. At the widest point it had a width of approximately 25 ft. and varied from that to nothing, the average width being not far from six feet. The vein appears never to have reached the andesite capping and is entirely contained in the slate, none of it having been scored away by erosion. The limits of this vein are characteristic, the first indication being the splitting up and 'fingering out' of the quartz, this being followed by

gradual replacement of the quartz stringers by the shales and finally the disappearance of all signs of a vein. The dimensions of this vein, as developed, showed it to have a longitudinal extent of 300 metres and a vertical depth of approximately 200. It was contained largely inside of the boundary lines of the Esperanza property. At the northern end, both veins were cut off by the main Esperanza fault, but at this point the value of the rock was small and the supposed continuations of the vein beyond the fault was of scarcely any value except at the extreme northern end of the property. Here good ore again occurred, though less extensive than in south of the fault.

The No. 2 vein was much less extensive than west vein No. 1, and as before mentioned, contained no appreciable gold, except at one point between the fourth and fifth levels where a small bunch of payable ore was found.

A curious feature in connection with the opening of these rich veins from which millions of dollars were extracted, is the fact that some time in 1897, a cross-cut was driven west on the third level which passed through both west vein No. 1 and west vein No. 2 but at a point where assay values in the first named were small and it was not, therefore, followed. A few metres to the north of this point the ore in vein No. 1 was worth \$100 per ton, and a few metres of driving would have largely changed the subsequent history of the mine, as well as given to the world the millions which came from these veins, at a much earlier date. However, the drift was not driven and the enormous wealth laid hidden for some seven or eight years more before it was finally found and handed out to the stockholders of the Esperanza Mining Co. The moral of this circumstance was not lost, however, and since that time no vein found in Esperanza ground has laid undeveloped for any great length of time.

In the meantime the development of the main San Rafael vein had not been neglected and several orebodies of considerable extent were opened in the north section of the mine, adding largely to the tonnage in sight, but as the ores were comparatively low grade, the value of the gold and silver content was naturally much less than that of the ores taken from the west veins, although the gross and net results derived from the ores of the San Rafael vein have reached exceptionally large figures.

Development on the San Rafael vein in the lower levels have been disappointing as regards finding valuable ore, there having been nothing of value found (up to the beginning of 1908) on the ninth or bottom level. Even the vein itself appears to be nearing its end. On this bottom level, the walls in both north and south sections of the mine are the same: andesite on the foot-wall and shales on the hanging wall, and the quartz vein at this point is not sharply demarked from the country rock, on the upper levels. It 'shades off' into porphyry on the foot-wall and slate on the hanging wall. All things considered, the outlook for payable ores with depth is not at all favorable, although there is still a possibility of its reappearance.

The diamond-drill was employed extensively for

prospecting purposes at the Esperanza mine, two Sullivan machines, type 'E' being used for this purpose, all holes being drilled horizontally and varying in depth from 50 to 500 ft. The ground penetrated included shales, quartz, and porphyry, the greater portion of the work being done in the shales and inasmuch as these last gave no 'core' and all information was derived from the action of the machine and character of the sludge flowing from the hole, the results obtained were not always conclusive. In many instances the holes were followed with cross-cuts in order to verify indications obtained with the drill.

Complete graphic records were kept of this work, showing location of hole, direction, inclination, when begun, when finished, character of ground penetrated, assays, total distance drilled, and other features. These were prepared as blue-prints and filed in the various archives of the company at El Oro, New York, and London. The following itemized costs of this class of work for the years 1904, '05, and '06 will probably be of interest:

UNDERGROUND, DIAMOND-DRILL PROSPECTING, ESPERANZA MINE.

| | —Average cost per foot— | | |
|------------------------|-------------------------|--------|--------|
| | 1904. | 1905. | 1906. |
| Labor | \$1.94 | \$2.50 | \$2.38 |
| Power | 0.47 | 0.27 | 0.16 |
| Carbon loss | 0.20 | 1.77 | 3.53 |
| Tools and implements.. | 0.01 | 0.04 | 0.01 |

*For six months.

GOLDFIELD MILL IMPROVEMENTS.

Written for the MINING AND SCIENTIFIC PRESS
By Our Special Correspondent.

The recent loss of the Combination mill is being offset by building an addition to the large mill of the Goldfield Consolidated Mines Co. A large portion of the additional equipment has arrived and the work of installation is now in progress. Probably the plant will be in full operation by December 20. All foundations and retaining walls have been in place for some time. The new machinery will not necessitate any additions to the present mill structure.

In addition to six 6-ft. Chilean mills, the equipment will include 26 Deister concentrators, four 8-ft. Callow classifying cones, a high-power electric pump, 2 agitators, and 2 elevators for use in supplying the Chilean and tube-mills. The grinding capacity of the plant will probably approach 100 tons per day, but the tonnage will be so regulated by the capacity of the cyanide plant as to be about 900 tons. The Chileans will be installed below the stamps on the second floor and close to the retaining walls carrying the greatest pressure. They will be divided into two groups of three each, situated at the north and south extremities of the plant. Immediately below the stamp-batteries and above the Chileans, and distributed at regular intervals along the length of the structure will be the 8-ft. Callow classifying cones.

The Deister tables will be divided into two groups of nine each on the floor with the Chileans, and two of four each at either end of the stamp-batteries. For the purpose of returning the over-size from the tube-mills to the classifiers the two elevators are being installed, the pulp going from the classifiers to the Chileans. The pump and compressor for the cyanide plant are on the lower floor. Direct amalgamation of the concentrate will replace largely table amalgamation below the stamps, thus saving the coarse gold before the product is sent to the cyanide tanks and effecting a saving of time in cyanide treatment. A further saving of free gold will be made by the use of blankets covering the second plates.

By the new system it is expected that a further saving above the present 94% will be effected. In the refinery, which is a part of the plant, all products of the mill are reduced to ingots of bullion or high-grade amalgam before sending to the United States mint at San Francisco, or to the Selby smelter. The process employed in treating concentrate was perfected by Mr. Hutchinson, superintendent of the Consolidated mill, after exhaustive experiments conducted during several months in the old 10-stamp Kinkead mill, on the south slope of Columbian mountain, which the company operated under lease as an experiment plant and laboratory. As a result of these experiments, the present refinery was constructed after the completion of the 100-stamp mill, and has proved highly satisfactory in operation, a saving in transportation alone of a large sum annually. The saving made in the big mill has been extremely satisfactory and with the addition being made the capacity will be notably increased.

Steel castings were first made in the United States for the Philadelphia & Reading railroad in July 1867.

MICA DEPOSITS OF SOUTH DAKOTA.

By DOUGLAS B. STERRETT.

*A number of mica mines are situated within a radius of 8 miles of Custer, South Dakota, in the southern part of the Black Hills. This area includes the better deposits of mica so far found, though some deposits occur 12 to 15 miles north of Custer, on the north side of Harney Peak. Previous to 1906 the production of mica in South Dakota had been small for several years, being often only that obtained from assessment work on the claims, but in that year the Westinghouse company took up several mines and prepared for systematic and extensive work. The success of this company has raised South Dakota to second rank among the mica-producing States.

The geology and mineral resources of the Black Hills have been described by numerous writers. Of the reports on geology those of Newton and Jenney¹ and of Darton,² taken together, furnish an excellent description. The mica resources have been treated in the South Dakota Geological Survey reports and have been mentioned in a number of the annual reports on the mineral resources of the United States published by the Federal Survey. A booklet with geologic map by Samuel Scott,³ of Custer, South Dakota, serves as a useful guide to the general geology of the Black Hills.

The Black Hills are a group of mountains rising to a maximum elevation, in Harney Peak, of 7240 ft. above the sea, or 3000 to 4000 ft. above the surrounding plains. They form an oval uplift about 125 miles long from north-northwest to south-southeast and 60 miles wide. The core of this uplift is composed of highly metamorphosed slates, gneisses, and schists with granitic intrusions. This core of ancient rocks is completely encircled by strata of later formations, which dip away from the core on all sides and were evidently once continuous over its top as a dome.

The granite formation of the Black Hills has its greatest development around Harney Peak and southward to Custer. Other smaller bodies and the pegmatites, into which it appears to grade in some places, occur in various parts of the highly metamorphic areas. Much of this granite has a very coarse texture and in some places it is difficult to know whether to classify the rock as granite or pegmatite. The pegmatite occurs both in the metamorphic rocks and in the granite.

In the Black Hills as elsewhere muscovite mica of commercial value is found in pegmatite. In this rock mica occurs as an accessory mineral of more or less prominence, the essential constituents of pegmatite being feldspar and quartz. The feldspars

are commonly orthoclase or microcline, though a plagioclase, albite, or oligoclase is present in some pegmatites, and locally plagioclase is the predominant feldspar. Pegmatites thus have the same constituent minerals as granites, though generally deficient in biotite and lacking in other accessory minerals, as hornblende or pyroxene. The proportions of the constituent minerals vary widely, not only in different bodies, but even in the same body. In some places the mass is chiefly feldspar with but small amounts of quartz and accessory minerals; in others quartz is the principal mineral. The deposits of mica-bearing pegmatites around Custer probably have a more uniform mixture of feldspar and quartz than many of those in North Carolina. Around Custer, where the best mica deposits have been found, only one pegmatite in many carries sufficient mica to pay to work. J. A. Holmes⁴ estimates that in some portions of the New York mine mica composes 10% of the whole pegmatite, but that in others it forms not more than 1%. Figures given by Mr. Pyne, the present superintendent, show that the rough mica obtained along the walls of the pegmatite (the only portion worked for mica in this mine) amounts to 6 or 7%. The interior of the pegmatite at this mine carries very little mica, say 0.5%; this would give about 2.5% of mica in the whole mass of pegmatite.

The texture of pegmatite may be like that of coarse granite, sometimes called giant granite, or the individual minerals may be separated into large masses in different positions in the pegmatite. These masses may be irregular in shape or arranged in bands generally parallel with the walls, giving the mass a veinlike appearance, as in many of the mica 'veins' of North Carolina. The mica-bearing pegmatites around Custer show a tendency toward an evenly granular texture or irregular segregation of mineral masses rather than a banded structure. In much of the rock there is, however, a rough banded arrangement in the segregation of the mica crystals along one or both walls. This structure does not resemble that of a vein so much as where bands of a single mineral, as quartz or feldspar, occur. The crystal of feldspar and irregular masses of quartz may attain dimensions of several feet across in pegmatite.

The shape of pegmatite bodies is variable. Some are rather persistent in length and form dikelike or veinlike bands or sheets that can be traced for several hundred yards. Others are lenticular in shape and occur either in short thick masses or in long slender bodies. Many of the pegmatite masses are irregular in shape and are quite difficult to follow in mining. Some pegmatite bodies lie conformably with the schistosity of the inclosing gneiss or schist either through part or the whole of their extent; others cut across the bedding of the rock formations. In places the lenses or sheets follow the irregularities of the enclosing rock. In this way they may be interfolded with gneisses and schists, or bulge or elbow out abruptly. Pegmatites may range in thickness from less than an inch to many yards, and the lenses may vary in length from 2 to 20 or more times the thickness.

*Abstract from 'Contributions to Economic Geology, 1908', U. S. Geol. Surv., Bull. 380.

⁴Twentieth Ann. Rept., U. S. Geol. Surv., pt. 6; continued, 1899, p. 693.

The pegmatites observed around Custer exhibit many of the above described characters. Some occur in regular sheets whose outcrops can be traced for several hundred yards; others are typically lenticular. Some lie parallel with the schistosity of the enclosing rock and others cut across the rock. The general features of the pegmatites around Custer resemble those of dikes, the veinlike type being rare or absent.

The No. 1 mine of the Westinghouse company,

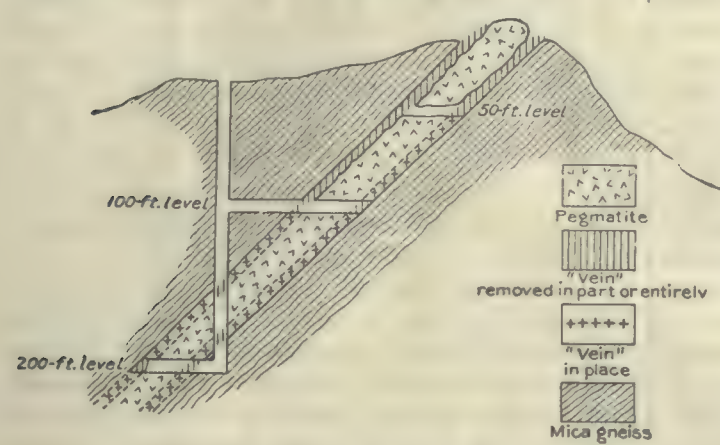

Fig. 1. Generalized Cross-Section of No. 1 or New York Mine.

formerly called the New York mine, is 5¼ miles southwest of Custer, between Hay and Four-Mile creeks. The mine is a small prominent hogback-like knob 700 ft. long and about one-third as wide.

The country rock is biotite gneiss and schist striking northwesterly and dipping about 50° southwest. The pegmatite is approximately conformable with the enclosing gneiss. The contact of the two is sharp, though with gentle rolls along the strike. The pegmatite has a thickness across the dip of about 30 ft. at the surface, 25 on the 100-ft. level, and 28 on the 200-ft. level. The mica occurs in two streaks or 'veins' in the pegmatite from 1 to 8 ft. thick along each wall. The interior of the pegmatite is nearly barren of mica or too poor to pay for working. Although the mica streaks vary in thickness and richness they are unusually regular for mica. The mica crystals occur in flattened or tabular blocks lying perpendicular to the walls of the pegmatite. The more common size of crystals ranges from 2 to 8 in. diam. and from 1 to 5 in thickness. Crystals a foot in diameter are not rare, while some measuring a yard across are found.

Fig. 1 represents a generalized cross-section of the pegmatite 'veins' and workings at the New York mine. The records show an average of 600 lb. of rough mica to 10 sq. ft. of 'vein' removed. The veins average from 5 to 6 ft. thick, say 5½ ft. If the weight of a cubic foot of pegmatite is estimated at 163 lb., it is found that the rough mica obtained averages about 6.6% of the vein matter.

The No. 2 mine of the Westinghouse company, formerly known as the White Spar mine, is 1¾ miles S. 40° W. of Custer. The vein is about 40 ft. thick at its outcrop, 25 at the 50-ft. level, and 18 to 20 at the 100-ft. level. The country rock is biotite gneiss, in which highly schistose beds are prominent. The pegmatite is roughly conformable with the enclosing biotite gneiss, though locally ir-

regular. The mica is distributed through the pegmatite with varying regularity. It was estimated that in one such portion southeast of the shaft on the 50-ft. level mica composed nearly 50% of the pegmatite. This mica occurred in blocks of all sizes up to a foot in diameter. The edge of one block of mica, or several blocks closely joined together, projecting from the floor, was nearly 5 ft. long and from 2 to 12 in. thick in different parts. The No. 3 mica mine is 3½ miles west of Custer and has not yet been actively developed. The No. 4 mine is five miles N. 15° E. of Custer, in a ridge separating two branches of the headwaters of French creek.

The Crown mica mine, of the Chicago Mica Co. is 2½ miles northwest of Custer. It has been worked by several open-cuts—the main one about 130 ft. long and 25 ft. deep and wide—a 20-ft. incline from the bottom of the cut, and 100-ft. shaft with a cross-cut to the 'vein', a drift, and a stope. The country rock is muscovite-biotite gneiss, with straight slaty cleavage in some places and a plicated structure in others, especially near the pegmatite bodies. The pegmatite is about 10 ft. thick, and is in part, at least, conformable with the schistosity of the gneiss.

The commercial applications of mica are numerous. The principal use at the present day is in the manufacture of electric apparatus. In the early days of

Fig. 2. Generalized Cross-Section of Crown Mica Mine, With Sketch Showing Relation of Pegmatite to Enclosing Gneiss.

the industry in this country the chief demand for mica was for glazing purposes, principally in stove manufacture. This has now become one of the lesser uses, along with the manufacture of gas lamp chimneys, and similar articles.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Correction.

The Editor:

Sir—In a recently published article in the MINING AND SCIENTIFIC PRESS regarding mining operations on the Mother Lode in Amador County, Cal., the writer made a misstatement regarding the Bunker Hill mine, namely, that the Bunker Hill had come into prominence within the year by beginning to pay dividends after a long period of unsuccessful operation. This was an error, as the Bunker Hill has recently paid its 39th consecutive monthly dividend and on December 15 will pay dividend No. 40, and an extra, No. 41.

Miners' Unions.

The Editor:

Sir—In your editorial, December 11, on the Homestake strike you contrasted the Western Federation of Miners and the United Mine Workers of America, greatly to the advantage of the latter. What you have said is accurate enough, but it may be helpful to point out some of the reasons for the broader outlook of the coal miners' union, despite the well known fact that its members are in general both poorer and less well educated than are the members of the Western Federation. Indeed, the United Mine Workers is largely made up of the 'ignorant foreigners' we are so accustomed to blame with all our troubles. The Federation has a much higher percentage of the native born among its members. Average wages for metal miners are undoubtedly higher than for coal miners, and the opportunity for individual advancement is quite certainly better. The members having these superior opportunities, the Western Federation ought apparently to be the better managed organization. The reason that it is not lies deep. Unions are an expression, as well as a cause of the growth of 'class consciousness'. The coal miners are mainly of a class that have been laborers for generations and expect to continue to be laborers. Expecting always to stay in the mines and expecting their sons to follow them in the work, they have determined as far as possible to improve the conditions under which they work, and their own economic position as workers. The metal miner, on the other hand, regards his position as temporary. He is usually looking forward to 'getting in on a lease' or to 'getting a fat contract', or at least to getting a grub-stake so that he may go prospecting. The number that expects always to remain in the mines working for days' pay is relatively small. As a result, their attitude toward the conditions of mining is different, and their sense of responsibility is less. What does a row more or less matter so long as one only means to stay a short time anyway? It is the universal experience of mine managers that married

men, men who have children, and men who own homes, are less easily led into stampede strikes, and are more reasonable in their attitude.

Another great difference in the two fields lies in the fact that coal mining is a competitive business in which the rational organization is by districts rather than by mines. All the operators as well as all the men in a given district have much the same conditions to meet. The units are larger and the men from different mines live in the same or adjacent towns. Inter-mine organization is therefore easier and in labor unions, as in other business organizations, growth in size and importance brings a sense of responsibility. The main factor, as I believe, in the better position of the United Mine Workers is that the organization subserves a real economic function, and that this was early discovered and utilized by a certain group of operators.

Coal mining, as already stated, is competitive, and competitive, it may be added, to a degree that the Western metal operator knows nothing of. The margins are small and the fight of district against district for the common market is intense and unremitting. The United Mine Workers of America originated in the longwall field in northern Illinois. The discovery and opening of the thicker beds of coal in the southern part of the State led to such cheap production as threatened the total extinction of an old and well established industry in the field nearest Chicago. Wages and profits went down to the point where both men and operators might as well fight as starve. This condition, as always, brought out real leaders, and the net result was that the northern operators supported the union in return for the latter organizing the southern miners and forcing wages to a point that equalized competition. The discovery of this power of the union to equalize competition gave it new place and dignity, and was, I believe, the prime factor in its growth. Today in the coalfields the prices paid labor have less relation to local supply and demand or to the difficulty of the work, than to the other costs of coal production and distance to market. Wages and freight rates are adjusted so as to give, as nearly as may be, a fair field and no favors in competitive markets. If some operator or district secured a reduction of freight rates a corresponding increase in wages is apt to follow.

In the meantime a well organized machine has been built up by both operators and miners, for the conduct of negotiations and settlement of difficulties. Collective bargaining, because of widespread uniformity of conditions in the coalfields, is applicable to an extent which seems impossible in metal mining. The result is that large problems are considered on both sides, and here, as elsewhere in American life, large problems bring out large men. It has repeatedly happened that a miner who was a true fire-eating radical when in the ranks has mellowed and broadened as he worked his way to the top, until, as a responsible officer, he was excellent. The operators have found, almost without exception, that ex-union officers make the best commissioners in behalf of the employing organizations. They know the game, and they have the confidence of the men. It is a curious

and interesting commentary on the situation that this employment of ex-union officials to treat with the men on behalf of the operators has led to almost no charges of bad faith.

All this is interesting only as it throws light on the Western situation. These conditions are different in many particulars, but what I should like to especially point out is that as the coal operators came to trust and work with their men, the latter have responded to the treatment. This much may, I think, be fairly claimed without in any way attempting to justify all of the acts of the union or its officials. Progress toward better conditions industrially is slow, as evolution was in nature, but if it be progress we can forgive the persistence of an occasional vermiform appendix.

OBSERVER.

Berkeley, California, December 13.

Pan-Americanism.

The Editor:

Sir—At the end of the Spanish-American war, Pan-America was but a phrase, a satire or a jest, and it is notable and notorious that during that war Spain held the sympathies of quite the majority of the South American countries. Territorial aggrandizement was the imputed motive of the United States in precipitating the war with Spain, and such a policy, it was believed, would jeopardize the independence of Latin-American governments. True, the past activities on the part of the Government of the United States to disillusion the South Americans of these erroneous conceptions in regard to our foreign policy, have modified and alleviated the situation, but there still remains, due to this failure to comprehend our foreign policy, some shadows of the old sentiment, that the United States stands as a menace to the continuation and preservation of distinct individuality on the part of Latin-American countries.

The causes for this misunderstanding appear not to be at all difficult to grasp, and may be safely attributed to the lack of direct and profuse intellectual contact with the United States coupled with the reliance of these countries for intellectual stimulus upon France and Germany—a medium through which facts or attitudes may readily be refracted or distorted. The beginning of intellectual intercourse with the United States may be noticed in such concrete forms as the Pan-American Scientific Congress and the Bureau of American Republics.

That there is a permanent Pan-American spirit—and that such a spirit of paternal co-operation is the inevitable outcome of environment and conditions, are, in my mind, two facts. True, intellectual stimulus has been and is of a Continental source, as is also the major portion of foreign commerce in Latin-America. Stranger still are the ethnological features of similarity in language, customs, and antecedents. It is a matter of history, that, generally speaking, the northern and southern continents in the Western Hemisphere were occupied by Europeans simultaneously—and, with similar motives. The north ultimately founded a single nation composed of several States. The colonists of South America, on the other hand, did not succeed in forming a federation or even a confederation. The more speedy adaptation

of the English to conditions as they found them is not surprising, as well as the failure of speedy adaptation to environment and conditions on the part of the Spanish colonists. The political tenets and beliefs of Spaniards and Portuguese are not to be reconciled with conditions in Latin-America. The history of Latin-America is characterized throughout by the struggle between the traditions and customs of Europe and conditions of life made necessary by immigration. It was practically predetermined that these colonists, in no way prepared by previous training in democracy, should find adaptation to their environment a difficult matter, and that it should necessitate struggles to adjust themselves to this new scheme of things. From totally dissimilar political institutions and social forms, Latin-American countries have developed forms of government, singularly similar to that of the United States.

Forms of government and politics are not now, however, the serious problems demanding solution in Latin-America, but rather social, educational, and economic problems. These are well exemplified by the present state of affairs in Costa Rica. The laboring classes are awakening to a consciousness of importance and power, and especially to the realization or appreciation of the benefits of an educational system embracing all classes. The readjustment of social order, which surely will follow the propagation of such ideas, is causing stresses and strains in the members of the social structure, and it is to be hoped that when the social structure is at last completed the thrust and tension will have been so harmoniously adjusted that equilibrium will be assured.

Extensive intellectual contact between the two continents in the Western Hemisphere is so far lacking. It is true—but difficult to imagine—that, as a whole, the United States completely fails to recognize the importance and extent of the influence she wields in South America. But I presume this seeming indifference may be attributed to the fact that such an ample field is afforded at home for the development of every activity; and, too, we are prone to estimate a country first upon its commercial possibilities. The advance movements in art, science, and morals in the southern republics have not been forced upon our consciousness.

The positive experience of Germany and the negative experience of Great Britain have demonstrated that in Latin-America the commercial possibilities for foreign capital depend upon the development and maintenance of a close sympathy, moral and intellectual bands, and ties of friendship. South Americans fully appreciate that there exists in the United States, due to both ignorance and misinformation concerning their affairs, if not an indifference bordering on hostility, a decided prejudice. At the same time their minds revert to the United States as their natural ally. Unity between western governments such as would presage ill success for any policy of territorial aggrandizement upon either the part of Europe or the Orient, is of utmost importance to all concerned, and such unity must rest on the firm basis of friendship and close intellectual sympathy.

LEE FRASER.

San Mateo, Costa Rica, September 30.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Power to the amount of one brake-horsepower per hour is generated from 1 to 1.25 lb. of coal, or from 3 lb. of wood in ordinary gas-producers. The gas contains about 80% of the original heat-energy of the fuel.

Gas-engine efficiency under the best conditions may reach 27% of the fuel-value of the gasoline or distillate. This, however, is a high figure. Ordinarily 20% will be considered good work. About 45% of the fuel-value of the hydro-carbon is lost in the exhaust, and from 30 to 35% in the cooling-water.

Resins are deleterious in the amalgamation of gold. They also cause foaming of the water and interfere with concentration. Resin may be introduced into the pulp by shavings and chips from the setting of mine timbers. Some explosives also contain resin, and unless the detonation of the powder is complete, unconsumed resin comes to mill with the ore and reduces the extraction of gold.

Carnallite, the commercial potash mineral, has the formula $\text{KMgCl}_2 \cdot 6\text{H}_2\text{O}$. It is generally massive, with conchoidal fracture, leaving a rough, granular surface, lustrous and greasy. The color is milk-white, sometimes reddish, and it is translucent to transparent. It is strongly phosphorescent. It absorbs water from the air (deliquescent); and has a bitter taste. It is as soft as talc, and has a specific gravity of 1.6. Douglasite is often associated with carnallite, its composition being $2\text{KCl} \cdot \text{FeCl}_2 \cdot 2\text{H}_2\text{O}$.

Castings, which were warped in cooling, may be straightened by re-heating and carefully weighting to bend them back. While still hot they may be moistened with water on the convex side which will cause that side to contract faster, and if carefully done, the casting may be brought true. In bending back by re-heating, the ends should be weighted, and the casting bent about as much in the opposite direction as the original warp. When cold, it will then be about straight.

Superheated steam is steam in a form analogous to air, that is, it exists heated beyond its critical temperature, so that no amount of pressure can cause its liquefaction, while remaining so heated. The advantages of superheated steam are mainly in the fact that practically all the extra heat put into it in superheating can be transformed into useful work. Steam formed in contact with water is saturated; by passing it slowly through pipes maintained at a high temperature all the water absorbed into the steam is vaporized.

Snake bites should be treated by ligaturing the bitten part at once with a tourniquet of cloth or rubber, and injecting locally a 1% solution of potassium permanganate. Alcoholic stimulants and

ammonia are absolutely harmful in critical cases. They are of value as restoratives only in cases where the person has not been fatally bitten. A special antiviral serum is now made at the Rockefeller Institute, New York, which is efficient in all cases except where an extremely large amount of the poison has been injected directly into the vein. This serum may be obtained from the Institute.

Producer-gas scrubbers are of two principal kinds, namely, tower-scrubbers, and mechanical. The former contain a series of shelves inclined alternately in opposite directions. Water trickles over these, dropping off the edges as a film through which the gas passes. The height is from 4 to 6 times the diameter. Mechanical scrubbers rotate, the gas passing through the contained rotating body of water. One form revolves slowly, the object being merely to cause a mixture of the gas and water. Another form rotates at high speed, centrifugal force separating the impurities from the gas.

Potassium salts in small quantities have been found widely distributed through the arid regions of the West, particularly in Utah. At one time a company was formed to work deposits in a porous sandstone in Hobbie Creek canyon, eight miles from Springville, Utah county, in that State. Another deposit was discovered near Milford, in Beaver county. A deposit is also known near Mount Hope, Eureka county, Nevada. Quite important beds occur in the vicinity of Humboldt, Nevada. There are possibilities of finding nitre beds in many parts of the desert regions of southern California, as well as in Nevada, Utah, and Arizona.

Amparo, as related to mines in Spain and Spanish America, is the maintenance of possession in mining property by compliance with the provisions of the law regarding taxes and other dues. In those countries title to the minerals is considered to lie in the State, which may cede such right to individuals, with all the privileges pertaining to absolute ownership. These, however, may be lost at any time by failure to perform all the acts specified by law in such cases. The existing systems of *amparo* are founded upon the old Spanish law (*Novísima Recopilación*) of the year 1387, Tit. 18, lib. 9, in which mining concessions were provided for on payment to the Crown of two-thirds of the gross output.

Potash salts are deposited on the evaporation of inland lakes in regions where the soils yield soluble potassium compounds. Tolman has found that the quantity of soluble potash salts was higher in the fine than in the coarser soil-particles in the arid Southwest. Granitic residual soils are particularly rich in potash. The potassium salts being more soluble than sodium salts, deposit above salt and gypsum beds on the drying up of salt lakes. At Stassfurt, Germany, the present source of the world's potash, the chief mineral containing that substance is carnallite, a hydrated double chloride of magnesium and potassium. The workable beds, lying above the great rock-salt beds, contain 16% of potassium chloride.

Special Correspondence.

WASHINGTON, D. C.

Suits Against A. S. & R. and State of Colorado. — Goethals to be Promoted. — Secretary of the Interior and the Geological Survey.

The Federal Government is considering beginning action against the A. S. & R. Co. to recover \$3,000,000. A proposal to enter suit against the State of Colorado for the value of 35,000 acres of mineral land, alleged to have passed into State control through misrepresentation, is also under consideration by the Department of Justice. Prompt action in both cases depends upon the decision of the Attorney General as to whether or not the cases are barred by the statute of limitations. The Interior Department last August forwarded a number of papers to the office of the Attorney General bearing upon the alleged claim against the A. S. & R. Co., and formally requested that suit be instituted. The papers are said to contain evidence that 'dummy entrymen' acquired title to many hundred acres of valuable coal deposits from the Government and disappeared from view when the titles to this land were safely with the smelting company. Since the documents were forwarded to the Department of Justice nothing has been done in the case, and nothing will be done until a certain test case, now pending in the West and involving the statute of limitations, is settled. Upon this decision, it is declared, rests the fate of this claim. Records on file at the Bureau of Corporations disclose 2000 acres of land, valued at \$200,000 and situated in Reilly Canyon, Colorado, as property "owned by or in the interest of" the A. S. & R. Co. The Carbon Coal & Coke Co. operates mines on the lands. The output thus far this year is said to be 250,000 tons. Titles to these coal lands, which passed to the smelting company more than six years ago, are said to have been the objects of particular enquiry by the Land Office agents during last year. The legal officers of the Interior Department, while admitting that the statute of limitations regarding land titles has operated to prevent the Government from regaining the lands, assert that it can sue for the amount alleged to have been obtained through fraud. As to the claim against the State of Colorado, the board of law review of the Interior Department has been unable to agree. The Congressional act which made Colorado a State in 1876 granted to it a large number of sections of the public domain, to be disposed of or used for school purposes or for the erection and maintenance of public buildings. A clause in the enabling act stated that lands of a mineral character should not be taken, and where inadvertently taken should be exchanged for lands valuable chiefly for agriculture or for timber and stone. Agents for the General Land office have reported that a great quantity of mineral land has been taken, and that the State has acquired and is leasing coal lands which will ultimately yield the State the sum of \$250,000,000 in revenue. It appears that these allegations of the Land Office agents have had the effect of starting an investigation to determine whether the Government, at this late day, can allege fraud and sue for damages. The officials have been unable to agree that the statute of limitations, which ordinarily works to clear titles of public lands which have passed to patent or have been granted by the Government, can be set aside in this case by a direct suit for damages, and the case has been laid before the Attorney General with the request for an opinion.

Lieut. Col. George W. Goethals, chief engineer of the Isthmian Canal, according to reliable report, may become the next Chief of Engineers of the army. Brig. Gen. W. L. Marshall, the present incumbent, will retire next year, and although Col. Goethals is not the ranking official in the engineering division, it is believed the President will desire to reward him for his work on the Isthmus. His promotion, it is asserted, would not require his relief from the canal direction, although he would not be on the Isthmus as much as at the present. President Taft has formally accepted the resignation of Joseph C. S. Blackburn as Governor of the Panama Canal Zone.

The annual report of Richard A. Ballinger, Secretary of the Interior, is considered here in Washington to be one of the ablest documents issued by the Government in some time, dealing as it does with a number of questions that loom large at the present time on the national horizon. Reviewing the work of the United States Geological Survey, the Secretary says: "The appropriation for the work of the Survey for the fiscal year aggregated \$1,590,680. While the work of the bureau was hampered by the fact that this appropriation is not large enough to carry out as fully as is desirable the varied lines of investigation and research, material and important results have been obtained in aid of the administration of the Department and for the information of the general public. This is especially notable with reference to public lands. Geologic surveys and investigations were continued during the year in 39 States and Territories, and over 55% of the appropriation for geologic surveys was expended in the 16 public-land States and Territories. In connection with the land classification work, about 16,000 square miles of supposed coal territory in the Rocky Mountain region was examined. Other work in the public-land States included commencement of the study of the phosphate deposits in Idaho, Wyoming, and Utah, the continuation of systematic detailed surveys of important mining districts in Colorado, Utah, New Mexico, Arizona, Nevada, and California, and of oilfields in southern California and Colorado and an extension of areal geologic work in these and other States. The general investigation of the water resources of the country has been continued along previous lines. The scope of the investigations has recently proved to be of national significance in connection with the temporary withdrawal. To withdraw from entry power-sites on the public domain intelligently would be impossible without definite information, but with the aid of the information which the Survey has collected during the past years, it has been possible to withdraw a large number of power-sites immediately, and many more can be withdrawn in the near future by reason of the fact that incomplete information is now available that can soon be made practically complete. Technologic work was carried on during the year in fuel investigations, structural material investigations, and mine accidents investigations. The first has included an enquiry concerning the fuels of the public domain and also the fuels for use by the Government. The larger part of the fuel used by the Government, aside from that used on board naval vessels, involving an annual expenditure of more than \$5,000,000, is now purchased under specifications prepared by the Survey, and the coal is sampled and tested by that organization. A like treatment is accorded crude petroleum and other mineral fuels used by the Government. In connection with the building and construction work, the materials to be used are now being generally tested by the Survey. These include materials for more than 300 public buildings in various States and Territories, recently authorized by Congress, involving an expenditure of over \$50,000,000. Structural materials for use in the engineering works of the Panama Canal, by the Reclamation Service, and by several bureaus of the Army and the Navy are also being examined. The investigations into the causes of explosions in mines have included examinations and analyses of explosives used in coal mining in the United States, examinations into the occurrence of explosive gases and dust and of those mines in which explosions have occurred during the year, examinations of so-called 'safety' lamps used in mines and of mine-rescue apparatus. The manufacturers of explosives used in coal mining have voluntarily submitted their explosives for testing by the Survey and have withdrawn from the market a number of explosives that failed to pass these tests. They have also made commendable efforts to increase the safety of their explosives even beyond the requirements of these tests and have shown a desire to carry out the wishes of the State Inspectors and the recommendations of the Federal engineers and chemists. In view of the fact that more than 85% of the fatalities in our coal mines are due not to explosions, but to other, though in many cases related, causes, it is important that the scope of the investigation be extended to include all conditions which make for greater safety in mining."

BUTTE, MONTANA.

Mining in Broadwater County.—Radersburg.—Ohio-Keating.—Ruby Gulch and Chouteau County.—Northwestern Metals Co. Mill.—Boston & Alta.

Radersburg was highly productive of rich, oxidized gold ore during the early days of mining in Montana. In the last few years development has extended below the oxidized section, into a clean, sulphide ore, running 35 to 40% silica, 52 to 56% iron, and averaging about 1 oz. per ton in gold. The ore occurs in three parallel vein systems, 1200 to 1500 ft. apart, in diorite. On one of the series of veins is the property of the Keating Gold Mining Co., of which Jesse B. Roote, of Butte, is general manager, and C. W. Pritchett, of Denver, consulting engineer. It is developed from two 500-ft. shafts, both of which are to be sunk 200 ft. deeper. The hoists and air-compressor are operated by steam, but as soon as the electric power line, now under construction, is finished from Boulder to Radersburg, all machinery will be electrically operated, the electrical equipment necessary to make the changes having been ordered. The ore-shippments from the Keating have been about two carloads per day for several months; during the last few weeks the ore shipped is said to have averaged \$27 per ton; prior to that it was considerably lower. Recent work on one of the veins has opened a high-grade streak of copper ore, equally high in gold; this copper streak occurs side-by-side with the regular gold-bearing iron sulphide. Buildings, equipment, and development planned for next year will call for the expenditure of \$100,000. M. D. Graves is mine superintendent. Among those most heavily interested in the property are Jesse B. Roote, Butte; R. B. Dear, Superior; Julius Barnes, Duluth; James McKee, and C. W. Newton, of Butte.

The other most active properties in the district are the Ohio-Keating and the Black Friday. The latter is being operated by the Montana Leasing Co., concerned in which are Nelson Bennett and associates of Helena. The development here has opened a shoot of ore that runs \$100 per ton. The ore shipped in the last year sold for \$85,000. The Ohio-Keating is sinking its shaft deeper, and operating hoist and air-compressor with gasoline engines. The country rock contiguous to the diorite is dolomite, and in it there is some prospecting and exploration. The ore is shipped to the East Helena plant of the A. S. & Co., and to the Butte Reduction Works, at both of which a low treatment charge is made on Radersburg ores, on account of their desirability as fluxing material.

The August mine at Landusky, and the Ruby Gulch mine at Zortman, both situated in the Little Rockies, 60 miles south of Dodson on the Great Northern, are new and successful gold properties. The August has produced \$340,000 since March 1, 1909, as the result of operating its crushing mill and cyanide plant at the capacity of 100 tons per day. The ore consists of a gold-bearing quartz-porphyry, mixed with fluorite and containing some tellurides. It is said to have averaged \$27 per ton, the recovery having been \$20. The principal metal in the tailing is said to consist of silver. The ownership of this property is divided, one-half belonging to the Ruby Gulch Mining Co., and the other half to William and Robert Coburn, and Louis Goslin. The Ruby Gulch Mining Co., controlled by Whitcomb & Phillips, operates a mill and cyanide plant that treats about 9000 tons of ore a month, that runs \$4 per ton in gold, the extraction being about \$3.60 per ton. Its gross production for 1909 will amount to \$350,000, approximately. The two mines are ten miles apart, and both are developed by means of adit levels.

The Northwestern Metals Co., organized by M. L. Hewett, S. T. Hauser, A. E. Spriggs, A. W. Burwell, and C. C. Titus, of Helena, and C. B. Stetson, C. H. Innes, P. F. Wood, and H. A. Nash, of Massachusetts, has made plans for a reduction plant of 100 tons capacity, which it is proposed to erect at Helena early next year. The purpose is to utilize the Baker-Burwell ore process of extracting gold, silver, lead, and copper which are associated with zinc sulphide. Those concerned in the project are interested in mines yielding

ores of this character in the vicinities of Elkhorn, Wickes, and Corbin.

The Boston & Alta Mining Co., whose work on the old Alta mine, close to Corbin, is in charge of C. C. Titus, is sinking a new shaft, which has attained a depth of 325 ft. The plan is to sink 1000 ft., then run cross-cuts to the old Alta workings from which a great deal of silver, lead, and gold was taken in earlier days.

DENVER, COLORADO.

Oil Boom at De Beque.—Coal Situation.—Recent Transfers of Property.—Clear Creek News.—Timber Preservation.—Reports from Cripple Creek.

The long deferred oil boom at De Beque in Mesa county is on. There have been two wells in the vicinity giving small quantities of oil for a number of years. As soon as the United States Geological Survey engineers issued a preliminary report on the district, the possibilities of the field became apparent, and speculators began to assemble. Two drill outfits are at work, and new leases are being granted every day. The operators in the northern coalfields have raised the price 50c. per ton on domestic fuel. This is causing considerable adverse criticism throughout the State. It is reported that the A. S. & R. Co., and allied interests, have purchased a large tract of coal land near Hayden. There is a strong possibility that the Federal Government will bring suit against the State of Colorado to recover some valuable coal lands in Routt county, which are alleged to have been acquired through misrepresentation. The site of the old Grant smelter in East Denver is being sold, piece-meal, to various railroads to be used for terminal purposes. Recently the Burlington has secured two and one-third acres, and the Union Pacific 15 acres. The Yukon group of 50 claims, on Boulder mountain, about three miles north of Silverton, has been sold by the Boston & Silverton M. Co., to W. B. Lowe. This is the largest mining deal of the year in this district. The St. Paul and St. Patrick claims near Georgetown have been transferred to the Lake Superior & Nevada Development Co. for \$10,000. This property formerly produced high-grade gold ore. The present owners will undertake development to find the main orebody. The Clear Creek district is active. More than 50 men are working over the old placers around Idaho Springs. Some good pay is being taken from the creek bottom near the Stanley mine. The Tanguay Mining company has installed new equipment in the Lincoln mill, and now has the plant in steady operation. The Phillips raise has at last connected the old Seven-thirty shaft with the Burleigh tunnel. The flow of water was not as large as might have been expected, because the shaft had been filled for some distance by lessees.

The preservation of mine timbers is being taken up by the United States Forest Service with several of the large mining companies. These furnish to the Service the kinds of timber which are available at the mine. After treatment and use the Forest Service will recommend a type of plant and methods of applying that preservative which will be most economical. If a company desires to act upon these recommendations the Forest Service will assist in the design of the plant, and will instruct the employees of the company in its operation. Further information can be obtained from the Denver office. The unusual amount of snow and the shortness of the month of November combined to lower the monthly production of the Cripple Creek district about 4400 tons below that of October. The total output was 59,215 tons, having a gross value of \$1,284,487. The heading of the Deep Drainage tunnel is now some 700 ft. into the granite under Beacon hill, and one of the main water courses may be penetrated any day. During the month large and rich orebodies have been uncovered in the lower workings of the Golden Cycle and Vindicator mines. Work has been resumed on the Prince Albert tunnel, where it had been suspended, while the Worcester system of ventilation was being installed. With a pressure of 2 oz. per sq. in. no trouble is experienced with the gas, even when the barometer is low.

LONDON.

Tin in Nigeria.—St. John del Rey.—New Found Out.

The tin resources of Nigeria have been attracting attention in London recently. Under the régime of the Niger company the tinfields of Bauchi province have been investigated and the railroad and steamboat facilities provided by the company have encouraged English prospectors. Oliver Wethered and his friends have this month formed a company called the Nigeria Tin Corporation with a capital of £100,000 to operate in that country. It was Mr. Wethered who was the active spirit in introducing London money for Dolcoath ten years ago. As co-directors on the present board he has a director of Dolcoath, another of Tronoh, and two officers of the Phoenix, so that the board is well versed in tin mining. No properties or options have actually been acquired, but there is plenty of business in prospect. Nigeria has long been known as a tin producer and the natives have washed the gravel and smelted the concentrate. The district where the gravel is found is too far inland for it to have been an attractive spot for English operations, but since the Niger company first took an interest in the subject some seven years ago, the extent of the deposits has been more accurately appreciated. The Niger company has done much development in the Narguta district in the Bauchi province, and in spite of the fact that only native washing appliances have been employed, as much as 500 tons of concentrate was exported during 1908. Hitherto the difficulty of transport has stood in the way of active development. At the present time a railway is being built from Baro, a town on the Niger, toward the Bauchi province, and trains are already running over 100 miles. By next June the total length of 216 miles should be completed. As an instance of the occurrence of this gravel it may be mentioned that a new district is reported where the gravel runs 3 lb. per cu. yd. in the upper wash, with 2 ft. of bottom wash running 10 to 60 lb. per cu. yd. News also is published that a lode rich in tin and copper has recently been found. Of the nominal capital of the company £75,000 is now being issued, and the whole of it, except the usual preliminary expenses of company formation will be available as working capital.

The St. John del Rey Gold Mining Co. has issued a report for the half-year ended August 31. At the Morro Velho mine 96,021 tons of ore was raised. Of this 4521 was sorted out and 91,500 sent to the 120-stamp mill. The production was bullion realizing £196,005, or £2 2s. 10d. per ton. Of the yield per ton £1 11s. 6d. came from the battery and 11s. 4d. from the 'No. 2' process. The total extraction was 87.15% of the assay value of the ore. The yield was about 3s. 10d. per ton greater than during the previous half-year. The working cost at the mine was £131,949, development £5703, London expense £1925, taxes and charges £9917. Out of the profits £2729 went to debenture interest, £5292 to the 10% preference shares, and £19,271 to the ordinary shares, being at the rate of 8d. per £1 share for the half-year. In addition £20,709 was transferred to capital account for new works. Since 1901 no less than £201,496 has been transferred from profits to capital account for expenditure on new work, and it is desirable to spend at least another £70,000 for the purpose of completing the Peixe electric-power plant and certain tunnels and a shaft. The directors have decided, therefore, not to pay off any more of the £77,970 outstanding bonds, but to convert them into second preference shares bearing interest at 10%. As regards the resources of the Morro Velho mine, it is reported that the lowest or sixteenth 'horizon' is opening up well, and that above this level the reserves amount to 860,000 tons, or over four years' supply. The tube-mill recently provided is still being run experimentally with a view to finding the most suitable lining. One of the most interesting ventures in connection with this company is the installation of an electric furnace for the production of iron and steel direct from the ore. Iron ore is plentiful, but iron and steel have been a serious item of expense to the company. The furnace is giving satisfaction and it is expected that its success will induce the Government to do something to develop the vast resources of iron ore at their disposal.

One of the newly developed properties in Rhodesia under the wing of the Consolidated Gold Fields group has recently been floated as a separate company. This is the 'New Found Out', which is near the Giant mine, in the Hartley district, 68 miles from Salisbury. The flotation was undertaken by the Enterprise company, which is controlled by J. and S. Well, and the Consolidated Gold Fields of South Africa. The latter's consulting engineer in Rhodesia, H. A. Piper, has reported on the property and considers that development has been carried far enough to warrant the expenditure of £65,000 on equipment, shaft-sinking, and further development. The formation is ferruginous sandstone which is heavily mineralized and contains much pyrrhotite and some arsenopyrite. The gold is finely divided and fine grinding will be necessary. Experiments are being made with a view to finding out the best metallurgical process of treatment. The developments have been pursued along the ancient workings, and sinking and driving to the extent of 3500 ft. have been done. The 70 and 250-ft. levels have been opened up, and a third level at 375 ft. has entered payable ore. Though the ore has not been blocked out, Mr. Piper considers that the existence of 33,000 tons, valued at 10.6 dwt., may be assumed.

NEW YORK.

*Metal Markets Active.—Copper Producers Report.—Mining Shares.**—Montezuma, of Costa Rica.—Tajo de Dolores.—Cactus Development Co.—Cobalt.*

In the metal markets, with the exception of tin and lead, nearly all lines are reported dull and unchanged. Tin reached a new high level for the year during the week, mostly on foreign demand, the price reaching \$32.15 per lb. for spot tin, as against the London quotation of £146 5s. per ton. The lead market is reported much stronger, having scored an advance of ten points, reaching 4½c. per lb. Spelter is steady with Mexican ores beginning to come into the market.

The official report of the Copper Producers' Association for December 1, showing the production and consumption of copper in the United States for November and the stocks on hand on December 1, compares with the two previous months, as follows. All figures being in pounds:

| | November. | October. | September. |
|-------------------------|-------------|-------------|-------------|
| Stocks | 153,003,527 | 153,509,626 | 151,472,772 |
| Production | 121,618,369 | 124,657,709 | 118,023,139 |
| Total | 275,127,995 | 276,130,481 | 253,655,704 |
| Domestic deliveries ... | 66,857,873 | 66,339,617 | 52,105,155 |
| Exports | 55,266,595 | 56,261,238 | 50,077,777 |
| Total consumption .. | 122,124,468 | 122,620,855 | 102,182,932 |
| Stocks remaining | 153,003,527 | 153,509,626 | 151,472,772 |

This report is much less encouraging than was anticipated. When the report of 30 days ago showed a decrease of over 2,000,000 lb., buyers, for a couple of weeks, came into the market more rapidly than during any month in the year with the exception of the one month of August when the decrease was some 32,000,000 lb. Now, however, it is quite apparent that buyers are again waiting and until some definite news of the large plans supposed to be under way in copper is announced, there will be little doing in the copper metal market.

The mining share market has been quiet during the week. The retreat which was in order after the rendition of the Standard Oil decision was followed by a waiting period during which the Eastern financial situation stood at attention awaiting the message of the President to the Congress just convened. The evident intentional avoidance by Mr. Taft of any utterance that could be deemed unsettling has served to re-assure financial interests and a strong upturn with a prevalent feeling of renewed confidence is at hand. The financial event of the past week, one of the most important indeed in recent years, was the purchase of Thomas F. Ryan's interest in the Equitable Life Assurance Co. by J. P. Morgan. While a strong undertone is plainly apparent, it is also quite evident that

business activity will not get into full stride until after the turn of the year. In metals this condition is especially true. Copper, which for the past year has been the centre of public attention in a large measure, is at a standstill. The buyers that came into the market upon news of the expected copper merger have ceased their activity now that plans are for the time side-tracked. Various steps are being taken in preparation for the merger, the most important being the deals whereby the Utah Copper Co. takes over the Boston Consolidated, with Ohio Copper probably included, and the purchase of a large interest in Miami by the Greene-Canaan. Neither of these has been wholly consummated, but it is accepted as certain that they will be in the near future.

The affairs of the Montezuma, of Costa Rica, a low-grade gold property, the shares of which are held largely throughout the East, have been attracting some attention. At a recent meeting of the stockholders, Mr. Johnson, the president, reported that the company was without funds and was indebted to him for some \$53,000 for loans advanced to carry on the work. S. F. Shaw, the new manager, made a report showing that the mills were operating satisfactorily and making a saving of 85 to 95%, but the real trouble seemed to be that the ores are too low in grade to admit of profitable treatment. Work is to be carried on for three or four months under Mr. Shaw's direction by way of experiment to test the possibility of saving a profit.

Walter Harvey Weed and Frank H. Probert, of New York and Los Angeles, have completed their examination of the Tajo de Dolores mine at Guanajuato, Mexico, made for the Proprietary Mines Company of America. The report computes the ore in sight at 388,000 metric tons, worth \$1,388,000, net. The Mines Company of America, operating the Creston-Colorado, at Minas Prietas, Sonora, Mexico, reports that the ore which it has been treating at its mill for the past month is running some 30% better than for any like period during the last quarter. There has been a report current that the company has opened a large body of ore of good grade, assuring several years of added life for the property. Unfortunately, confirmation of the report cannot be had from any authoritative source.

A report recently made for the Calumet & Hecla interests on the properties of the Cactus Development Co., near Globe, Arizona, is said to have been favorable. Horace J. Stevens writes to a friend in New York concerning the property: "The Cactus has excellent prospects of making at least as good a mine as the Miami, while developments to date warrant the prediction that it should develop into one of the very largest copper mines of the world." Cobalt figures as to production show that the records of previous years are already broken, but the camp furnishes little in the way of sensation at present. A campaign has been made soliciting the proxies of the Cobalt Central stockholders to be turned over to Adolf Lewisohn. Mr. Lewisohn has taken occasion to state that he never agreed to assume responsibility for the company's affairs.

TORONTO, CANADA.

Ontario Mineral Output.—Cobalt News.—Technical Education.

A large increase in the mineral and metallurgical output of Ontario is shown by a statement issued by the Provincial Bureau of Mines, covering the nine months ended September 30. The total value is given at \$16,763,742, as compared with \$12,185,511 for the corresponding nine months of 1908. The largest item is silver, the output of which amounted to 18,751,549 tons, valued at \$9,385,600. The shipments of ore from Cobalt amounted to 22,218 tons, as against 17,335 tons, the proportion of concentrate being considerably larger, so that the silver content of the shipments exceeded those of the same period last year by 6,170,089 oz. Other notable increases were in iron ore and pig-iron. The output of the former amounted to 205,262 tons of the value of \$473,770, an increase of 39,174 tons, while pig-iron was produced to the amount of 294,698 tons, valued at \$4,095,735, an increase of 105,411 tons. Shipments from Cobalt have since been well maintained, consignments for November amounting to 2447 tons. Among the few recent accessions to the list is

the Beaver which is now working in a vein of rich ore 12 in. wide on the 250-ft. level. The Nova Scotia is increasing its capital stock by \$500,000 the issue being offered to shareholders at 50c. in proportion to their holdings. The engineer's report presented showed that 1,600,000 oz. silver had been blocked which was expected to yield the first year about \$60,000. A cyanide and amalgamating mill is under construction which it is hoped will be ready by spring. Underground operations at the Green-Meehan have been resumed after a cessation of some months, and will be carried on throughout the winter. Development is to be vigorously pushed at the 200-ft. level, where some good discoveries were made. Operations have been retarded by the delay in furnishing electric power, which was expected to be procurable some time ago, but cannot be had before spring. The annual meeting of the Ophir was held at Cobalt on December 6, the financial statement showing \$116,000 in hand. Since the installation of the plant last June 1000 ft. of stripping has been done, disclosing four well mineralized veins. The shaft is now down 210 ft., and about 90 ft. of driving has been done on the 100 and 200-ft. levels. The Union Pacific has reached a depth of 125 ft. in the shaft on their Peterson Lake leasehold, and will sink to 200 ft. before cross-cutting. The Gifford Extension has its main shaft down 200 ft. with a 10-ft. sump. A contract has been let for 300 ft. of cross-cutting to reach a big 27-in. vein cut by diamond-drilling and afterward tapped at the 80-ft. level. Three good veins have been struck in the first 26 ft. of the cross-cut. The annual statement of the Coniagas shows \$128,477 cash on hand, and \$151,971 value of ore under treatment. The dividend payable amounts to \$120,000. At the Trethewey a concentrating mill with a capacity of 100 tons of ore per day is in course of construction and is expected to be ready in the spring. There are 45,000 tons of milling ore on the dumps, estimated to be worth over \$450,000, and the ore in sight is estimated at between 5,000,000 and 6,000,000 oz. The O'Brien mine, at Miller lake, in the Gowganda district, previously known as the Gates' property, has made two important finds recently. At 42 ft. in the cross-cut at the 100-ft. level from No. 2 shaft, a 6-in. calcite vein, carrying high silver content, was struck, from which ore is being taken. Another vein 2 in. wide of high-grade ore has been found in the east drift from the cross-cut.

Eugene Haanel has been notified of the proposed erection in Norway of a second electric smelting furnace by H. Boholm, director of the Cobber Mine & Smelter Co., of Trondhjem. The latter has requested Mr. Haanel to recommend some metallurgist capable of taking charge of the erection and management of the works, which is a noteworthy recognition of the work done by the Canadian Mines Department in perfecting the system. Technical education is receiving considerable attention at present both from commercial and industrial bodies and professional educators. It is fully recognized that Canada is considerably behind other countries in this important matter. The question came up in the Canadian House of Commons recently when Hugh Guthrie, M. P., moved a resolution favoring the appointment of a commission of enquiry to investigate the needs of Canada in respect to technical education, and report as to ways and means. He intimated that he brought up the subject at the request of the Canadian Manufacturer's Association, and the Trades & Labor Congress, and that it had the support of numerous boards of trade and other representative bodies. Expressions of opinion were almost unanimously favorable, but Mr. Mackenzie King, Minister of Labor, on behalf of the Government, brought up the objection that there might be a constitutional difficulty in the way of action by the Federal Government, the matter of education falling under the jurisdiction of the provincial governments. He urged that the Government must have time to consider this and other aspects of the case and moved the adjournment of the debate. This being carried practically shelves the proposal for the present. The constitutional objection comes rather late in the day considering that the Government has repeatedly made grants for educational purposes. But Canadian politicians are adepts in the art of 'how not to do it'.

General Mining News.

ARIZONA.

COCHISE COUNTY.

The November output of the Copper Queen smelter was 9,400,000 lb. copper, a slight increase over the October production. Throughout the month there was an average of $8\frac{1}{2}$ blast-furnaces in operation and 6 converters.—The Calumet & Arizona smelter turned out 4,500,000 lb. of copper with 4 blast-furnaces and 5 converters in November. The directors of the company declared a dividend of \$1 per share.—The Fairview Mining Co. has been incorporated to open a group of claims near Johnson. A shaft is down 100 ft. on the property and a contract let for an additional 100 ft. of sinking.—The adit at the property of the Bisbee Copper Co., three miles from Bisbee, is in 170 ft., and has cut three veins of silver-lead ore. Ralph Ingram, the manager, states that the company will drive a 2700-ft. adit to open the ore at depth.—Operations are to be resumed at the Red Cloud group, in the Dragoon mountains, and a shaft sunk several hundred feet. Frank Briggs is manager.—The Bisbee Coalition company is building a road to its property four miles from Bisbee and will install a boiler and compressor. R. J. Clark is manager.—At the Morrow and Chamberlain group, in the Paradise district, the shaft is down 142 ft., and the company will continue sinking till the 200-ft. point is reached and then cross-cut to the contact.

GILA COUNTY.

(Special Correspondence).—Work on the Cactus is progressing at the rate of 1000 ft. per month.—The plan of development is to cut the property into 200-ft. squares with the levels established 100 ft. apart. G. W. Pritchett is general manager and consulting engineer and T. W. Hamilton superintendent.—At a depth of 84 ft. the Jennie shaft of the Cordova Copper company's property in the Miami district has opened a sulphide orebody, assays from which place the copper average at 2%.—About 95 men are being employed on the property of the Inspiration Copper company which is now in charge of T. R. Drummond.—The Scorpion shaft is not at present in ore owing to the fact that the copper-bearing body dips sharply to the south and away from the shaft. At a depth of 275 ft. a cross-cut will be driven from the shaft to strike the orebody.—Two Star churn-drills are now at work on the property of the Boston-Miami Development company in the Miami district. Fred W. Hoar, of Globe, is superintendent.—At the annual meeting of the stockholders of the Superior & Boston Copper Co., held at the mine office in Copper Hill, December 6, the board of directors that has served for the past year was re-elected. The financial statement for the fiscal year ending September 30, 1909, showed the balance of cash on hand to be \$298,544. The expenditures for the past year have been \$673,453. The receipts were \$679,155.

Globe, December 11.

MCHAVE COUNTY.

The latest discovery made a few days ago in a large open-cut at the Bi Metal mine, three miles south from Kingman, almost insures its purchase by John Hays Hammond. Rich stringers of a hematite ore containing gold were found traversing the entire face; one of these is 18 in. wide, and assays from 15 to 72 oz. gold per ton.—The Golden Gem mine at Cerbat has been sold to an Eastern company, and the surrounding Vanderbilt, Flores, Columbus, Broken Hill, and Idaho mines have also been examined, and will, in all probability, be taken over.—In the San Francisco district the Ruth mine has been sampled for A. L. White & Co., of Lima, Ohio, who have a limited option on the mine.—George Hartman has bonded his claims in the Tom Reed district, to a party of Nevada men for \$50,000. Sinking will be started at once.—On the Klondyke mine, in the Virginia district, 6 ft. of \$6 free-milling ore were cut on a parallel vein several hundred feet from the main workings at a depth of 30 ft., while sinking for water.—L. D. Godshall, general manager of the newly acquired interests of the United States Smelting, Refining & Mining Co., has just

ordered 16 gasoline hoists to be used in developing some of the recent purchases.—A new orebody was opened by the drifts on the 300-ft. level of the Golconda mine while driving to connect the shafts. The company paid its fourth dividend of 1c. per share December 11.—Four Nissen stamps have been ordered for the Dixie Queen mine in the Virginia district, and a mill will be erected shortly.

PIMA COUNTY.

The Southern Belle group, ten miles from Oracle, has been taken over by a group of California men, and will be re-opened. There is a large mill on the property and considerable development was done in the mine before it was closed down about 15 years ago. F. L. McPherson will be in charge of operations at the mine.

YAVAPAI COUNTY.

The Arizona Power Co. has contracted to supply the Alvarado Mining Co. at Congress Junction with electricity for the mine and mill and is building a line from Prescott to the mine.—The Arizona Placer Co. has made the last payment on the Wagoner property at Walnut Grove and is to commence more active development.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence).—Mining engineers, believed to represent Colorado capitalists, examined the Eureka mine a few days ago. The Eureka has been idle for 30 years, but was formerly a noted producer. Mrs. Hettie Green, of New York, is the heaviest stockholder.—The Bunker Hill has reduced its monthly dividend to 4c.—Sinking at the Kennedy is progressing steadily. The vein is being opened at the 3300-ft. point, but development has not progressed sufficiently to determine its size or value.

Jackson, December 13.

(Special Correspondence).—Two Austrian miners were injured in the Keystone mine at Amador City by an explosion caused by tamping powder in machine-drilled holes with an iron spoon.—In the complaint of the Kennedy Extension Mining Co. in its suit against the Argonaut Mining Co., the former states that the Argonaut company has mined \$500,000 worth of ore from a vein that apexes in the Muldoon ground which the latter is operating, and asks that the value of this ore and \$200,000 exemplary damages be paid by the Argonaut company.

Amador City, December 13.

CALAVERAS COUNTY.

A 40-hp. G. W. Price Pump & Engine Co. gasoline engine is being installed at the Horswill Deep Gravel mine between Valley Springs and San Andreas to operate the hoist and pump. F. A. Horswill is superintendent.—Operations have been started for the winter at the Moosehead gravel mine near Sheepranch. Edward Rigney is at the head of the enterprise.—Operations have been suspended at the Washington mine on Indian creek.—Some good gravel is being opened at the old Benson mine near Northbranch.

KERN COUNTY.

(Special Correspondence).—The Kern Development Co. has completed its 3-compartment shaft to the old workings of the Big Blue and Summer mines and is about to commence activities. In addition to these mines the North Extension Summer, Lady Belle, Beauregard, Fronk, Bull Run, and Urbana, will be operated through the new working avenue. Eastern people are interested. R. L. Long is superintendent.—Oscar G. Rogers, of this county, has taken a lease and option for \$40,000 on the McCreadle group of claims in the Amalie district.—Tungsten mining in a small way continues active in several districts.

Bakersfield, December 10.

MARIPOSA COUNTY.

The adit at the Hite Cove mine opened a shoot of rich ore. There are 35 men working at the property.—The shaft at the Champion mine has cut several streaks of high-grade ore.—R. O. Reick found a \$5000 pocket near Coulterville.—Joseph Kolbak is to install a 2-stamp mill on his claims on Saxon creek.—The Mountain King Mining Co., operating a group of claims eight miles above

Bagby, on the Merced river, are building living quarters for the men and are planning to enlarge the mill.

MONO COUNTY.

The Gray Butte Mining & Milling Co., operating southwest of Benton, is to start a new adit that will give about 300-ft. depth on the vein. The samples from a number of open-cuts and short adits have shown the vein to be 6 ft. wide, and to assay from \$14 to \$45 per ton.

NEVADA COUNTY.

(Special Correspondence).—The shaft at the Empire is going down rapidly. Four machine-drills are running on three shifts.—The adit at the Le Duc is in 850 ft. A narrow seam of quartz has been cut and it is expected to intersect the main vein within 30 days.—The 5 by 15 ft. vertical shaft at the Brunswick is down 115 ft. C. A. Mallen is superintendent.—At the Idaho-Maryland, development is principally on the 500-ft. level.—The 300-ft. adit at the Twin Sisters has cut a body of milling ore. Assays are reported to be about \$15 per ton. George Harty is superintendent.—Good ore is coming from the 300-ft. level of the Austin.—At the Pittsburg the shaft is going down rapidly. The mill is running steadily on ore from the 400-ft. point.—It is rumored that the management of the Murchie is contemplating an early resumption of activities.

Grass Valley, December 13.

Supplies are being hauled to the Gold Canyon mine at Moore's Flat and operations are to be resumed at once. Charles W. Smith is superintendent.—The drift at the

stalled. As soon as this installation has been completed the company will install machine-drills in the mine.—Operations have been suspended at the Oakland mine owing to the heavy snows.

TRINITY COUNTY.

The Trinity Dredge Co. has been organized to build a dredge on the Trinity river near Lewiston. The company owns 60 acres of rich gravel and a water-right from which it will generate power to operate the machinery. E. L. Smith will be in charge of the work.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Charter-Raton Mining & Milling Co., operating on Breckenridge mountain, has purchased from J. R. Gemmill the Louis B. and J. J. claims. The LaMoe adit has been advanced for 1250 ft., and the veins of these claims lie only a short distance ahead of the present breast. J. J. Bonner is manager.—W. M. Cooper, manager for the Capital Mining & Milling Co., operating on Griffith mountain, is doubling the capacity of the 125-ton concentrating plant. The basement is being enlarged and 12 Card tables will be placed in position during the next week.—Cavanaugh & Co., of Silver Plume, have taken a lease on the Vulcan mine on Sherman mountain.—The chemical laboratory at the Malm chemical-electro plant was started last week. S. A. Ionides, chemist in charge, is now sampling ore from several mines.

Georgetown, December 11.

(Special Correspondence).—The Almaden Mining Co., operating in Spring gulch, has secured the Shaffer group of 9 claims. With these holdings the company controls 24 claims, giving it possession of all property lying along the course of the Blazing Star adit for a distance of 3000 ft. A. R. Comstock is manager.—J. W. Boyd has secured control of the Lexington mine and a force of men is now employed in placing the workings in condition preparatory to shipping.—Work was resumed last week upon the holdings of the Crown Syndicate Mining Co. in the Lamartine district. F. Lally is in charge.

Idaho Springs, December 10.

GILPIN COUNTY.

(Special Correspondence).—The Slide property at Russell gulch is being unwatered and the shaft will be sunk to the 300-ft. level.—R. Pearce & Co., of Nevadaville, have taken a lease on the Missouri property.—During the month of November the Frontenac Mines Syndicate shipped 2000 tons of ore. Of this amount 1800 tons was treated at the company mill, the balance being sent to the Modern smelter. It is stated that henceforth the output will be at least doubled. H. P. Lowe is manager.—The Denver Quartz Mill & Crusher Co., is to build a 75-ton mill to handle custom ore.—The Milton property on North Clear creek is being cleaned out and re-timbered.

Central City, December 10.

LAKE COUNTY.

Operations have been again started at the old Dolomite shaft in the Leadville district and a 100-hp. boiler installed by the lessees. The shaft is down 400 ft. and it is the intention of the present operators to cross-cut on that level.—There has been considerable activity in Half Moon gulch the present season and plans have been made to drive an adit in the spring that will cut the ore at depth.—At the Progressive mine on North Fryer hill the drift on the lowest level is being driven south to open the shoot recently found on the level above.—The New Jersey Zinc Co. is shipping 75 tons of zinc ore per day from the dumps of the A. Y. & Minnie mine.—Local men have secured a lease on the Hopemore claim and have shipped three lots of ore to different smelters.—The face of the Yak tunnel is beyond the Resurrection No. 2 shaft and will be soon under the Diamond ground.—Nine carloads of silicious ore per month are being shipped by lessees from the No. 2 Penn shaft.—The Printer Boy shaft has been cleaned out and re-timbered and the lessees are now driving in ore.—The Bald Mountain Mining Co. is to sink 200 ft. from the adit level and cross-cut the vein.

Trinity County, California.

Oustomah, which recently opened the ore on the 900-ft. level, has been driven 90 ft. on the shoot, the vein widening to 2 ft. A raise will be started from the end of the drift shortly. The 10-stamp mill is running steadily on good ore.—Operations have been started for the winter at the Jefferson gravel mine near Remington hill. E. K. Benchley is in charge of the work.—Some high-grade ore is being opened on the lowest level of the Red Ledge mine near Washington.

SHASTA COUNTY.

A \$28,000 gold bar was brought to Redding as the result of the monthly clean-up at the Midas mine at Harrison gulch. L. A. McIntosh is manager for the company which is working 110 men.—Erik O. Lindblom has purchased the Milkmaid mine at French Gulch from the Western Exploitation Co. for \$300,000. There are five claims in the group which has been worked from 1857. The mine was closed down in 1898 and remained idle till two years ago when it was bonded by H. F. Musser and re-opened.

SIERRA COUNTY.

The compressor and power plant has been hauled to the Gray Eagle mine at Gold Point and are now being in-

OURAY COUNTY.

It is reported that the Bright Diamond mine, north of Ouray, has been sold and that the new company is considering plans for the erection of a smelter.—The old workings at the Wedge mine have been re-timbered and the operators are now ready to begin shipping.—A rich vein of silver ore is being opened at the Black Girl mine under lease to Fred Herzinger.

SAN JUAN COUNTY.

At the Bonner mine, in the Silverton district, G. Crossman is installing an Ingersoll-Rand compressor and stope-drills, General Electric 100-hp. motor, three No. 7 and three No. 5 Leyner drills. The value of the ore is about \$50 per ton, though it is complex, containing considerable zinc.—At the Homestake mine belonging to James McNamara, on Mineral creek, a 9-ft. vein that assays \$29 per ton is being opened. Two feet of the vein is high-grade ore going over \$50 per ton.—Two streaks of high-grade ore were cut by the raise in the Thunder Fairview property. George H. Bibb is manager.

TELLER COUNTY.

A sub-lease on the Conundrum mine has been secured by S. A. Worcester, of Victor, on a 25% royalty basis.—The Jerry Johnson Mining Co. paid \$25,000 dividends on December 15. This is at a rate of 1c. per share. The Elkton Consolidated will distribute \$50,000 or 2c. per share on December 24.—The lessees of the Kitty Lane property have opened a good body of ore on the 250-ft. level and are installing an electric hoist.—A new orebody has been opened on the third level of the school land operated by the School Section Leasing Co., and several cars of ore shipped that assayed from \$18 to \$24 per ton.—The November production of the Vindicator Consolidated company was a little over 3000 tons of ore having a bullion value of \$100,000.—The Alabama Mining & Leasing Co., operating the Pharmacist mine on Bull hill, has opened a new orebody 100 ft. south of the shaft. During November the company shipped 240 cars of \$20 ore.—The United Gold Mines Co. has declared a dividend of 1c. per share amounting to \$40,000 to be distributed on December 20.—Gilder, Stetson & Williams, of Victor, representing Chicago capitalists, have secured an 18 months' lease on the Last Dollar mine on Bull hill.

IDAHO.

IDAHO COUNTY.

At the American Eagle mine, near Elk City, under lease to A. W. Boyd, a small force is at work underground getting the old workings in shape for production and opening new ore. The mill will not be started till spring.—At the property of the Dixie Royal Mining Co. two veins have been opened this season and it is probable that the company will erect a mill in the spring.

MICHIGAN.

The first weekly shipment of ore by the Lake Copper Co. produced even better results than the test run made a few weeks ago. In the trial run 80 lb. of mineral per ton of rock was obtained as compared with over 82 lb. in the present shipment, while the amount of refined copper was 59.33 lb. as against 60.9 lb. in the last run. The ore for the test was taken from various parts of the mine that have been opened with a view to obtaining a fair idea of the average value.—The New Baltic Co. has drilled into an amygdaloid vein for a distance of 105 ft., equal to about 75 ft. in cross-section, all showing some copper and 7 ft. of exceptionally rich. Articles will be filed at Lansing for the incorporation of the New Baltic Copper Co., with 100,000 shares, \$25 par. No arrangements have been made as yet for floating the new company. In Section 12 the exploration diamond-drill has made no progress since November 5 on account of caving ground necessitated frequent cementing.

MONTANA.

SILVER BOW COUNTY.

(Special Correspondence).—W. A. Clark, owner of the United Verde copper mine in Arizona and several large mines in Butte, appears to be in opposition to the proposed

copper merger because of his mining troubles, or threatened troubles, with the Amalgamated company over mining rights in the Butte district. It is a notorious fact that the Clark copper, produced in Butte, costs more per pound than any other turned out in the district, chiefly because of old and antiquated methods still in use at his plants. Clark has recently purchased a large tract of land at Bearmouth, together with a large water-right and it is reported that he intends to build a smelter there, presumably to treat the ores of that district.—The Tuolumne Copper Co. has ingeniously met the claim that it is mining on the Jessie vein of the North Butte company, which it is opening from the 1000 to the 1400-ft. level, close to the south-side line of the Jessie claim. When it was first charged that the Tuolumne was trespassing on the North Butte vein, a strenuous denial was entered and the claim set up that the vein worked by the Tuolumne was an independent vein having its apex in the Tuolumne ground and had no connection with the Jessie vein. Later the Tuolumne miners, in working on the vein in question, broke into the workings of the North

Anaconda Hill, Butte.

Butte on the Jessie vein. Now Tuolumne admits that it is the Jessie vein, but claims the vein belongs to Tuolumne ground, and that instead of having its apex all the way in the Jessie claim, it crosses the south boundary line of that property and for more than 900 ft. is entirely within the Tuolumne claim. The North Butte people had contended that the apex was so far north of the Tuolumne that there was no question about its occurrence on the Jessie claim. Now, however, the Tuolumne people put the issue up clearly that it is a question of the ownership of the apex and on this the controversy will probably be fought out. No action has yet been brought to determine the rights of the parties, but both are active in making developments and surveys preparatory for the legal fight that seems inevitable.

Butte, December 11.

NEVADA.

CLARK COUNTY.

A contract has been let to sink the shaft on the Big Six property, near Searchlight, to the depth of 175 ft. James Wilson is manager.—Kerby & Gaines, the lessees on the Good Hope group, have opened a streak of rich ore at a depth of 25 ft., and a hoist will be installed.—The Quartette Junior company is to resume sinking at an early date.

ESMERALDA COUNTY.

The Pittsburg-Silver Peak Mining Co. is adding 20 stamps to its mill and is arranging to pipe water from the Valcalda property to the town of Blair.—W. F. Gray and associates have secured a five-year lease on the Gold Bar claim of the C. O. D. Consolidated company, at Goldfield, and will erect a 50-stamp mill on the property.—There are several sets of lessees operating on the Atlanta ground, and it is hoped to find the extension of the Clermont vein.—In the Daisy all the ground has been leased and about 25 tons per day of \$30 ore is being hauled to the mill.—A 15-hp. gasoline hoist has been placed on the Goldfield Banner lease on Booth ground and the shaft unwatered. Cross-cuts will be driven from the 150-ft. level and if the ore is not found at

that point the shaft will be sunk an additional 100 ft. and the ground prospected from that level.

LANDER COUNTY.

(Special Correspondence).—The Austin-Manhattan is opening excellent ore in the Frost shaft and Jack Pot mine.—L. D. Mills, of the C. W. Merrill Co., of San Francisco, is conducting experiments in the old mill prior to the erection of the new plant.—The lessees on the Peerless report the opening of a 2-ft. vein of \$120 ore.—F. L. Judd and associates, of Cleveland, have purchased a group of claims in New York canyon. The same people are working the Patriot and Roosevelt and will drive an adit on the True Blue claim to cut the Patriot vein.—The Mennis lease at Bannock reports the uncovering of bonanza ore. The shoots are narrow, but the ore assays well.—French capitalists have become interested in the Galena group of 16 silver-lead claims and are planning to drive a 3000-ft. adit to unwater the property and provide water power for a large mill. E. G. Labadie is manager.

Austin, December 9.

NYE COUNTY.

(Special Correspondence).—The mill of the Tonopah Extension is rapidly nearing completion, and it is now thought that the plant will be in operation by February 1. John G. Kirchen is manager.—Midway is opening new ground in the north portion of the 435-ft. level. Nearly 200 tons per week are being sent out from the upper workings.—The Hargrove-Bell lease on the Diamond Queen reports the uncovering of a 2-ft. vein averaging \$311 per ton at a depth

Montana Tonopah, Goldfield.

of 100 ft.—The Mayflower has opened a 3-ft. body of \$25 to \$66 ore on the 400-ft. level.—The District Court of Nye county has ordered that the Solid Gold mill, at Round Mountain, be deprived of the waters of Shoshone creek, as far as relates to the Daisy water rights, and establishes the rights of Round Mountain Fairview to 2465 in. of water from the creek. The Fairview mill will resume operations within a short time. It is expected that sufficient surplus water will be developed to enable the Daisy to continue the steady operation of its Solid Gold plant till spring.—The Manhattan Mining & Leasing Co. is to start its Canyon mill. Ore from the Little Grey and Eagle claims will be handled at first.—The Four Leaf has commenced the washing of gravel at the Gold Pan and Fairview claims. The shaft is down 93 feet.

Tonopah, December 11.

The Montana Tonopah company is doing considerable development work on all levels of the mine, especial attention being paid to the western part of the property in order to pick up the extension of the Triangle vein.—On the Sand Grass claim of the Tonopah Mining Co. a 3-compartment shaft is to be sunk to the 2000-ft. point and the claim prospected from that depth. This shaft will be 2000 ft. west of the Red Plume shaft, which at present is the most westerly working on the property. On the 1500-ft. level, the company has installed a diamond-drill.—One carload of ore

per day from the development work at the MacNamara is being shipped to the Balaklala smelter at Coram.—Frank Peterson and associates sent 500 tons of ore to the War Eagle mill from their lease on the Stray Dog mine at Manhattan.—On the Swanson lease on Earl ground the lessees have the shaft down over 150 ft., and are stoping on the 100 and 150-ft. levels. There are approximately 1000 tons of ore on the dump that will average \$20 per ton.—A run of 400 tons from the Rose-Nash lease, on Union No. 4, was put through the War Eagle mill. The ore assayed from \$12 to \$20 per ton.—The Round Mountain Mining Co. is to pay its seventh dividend of \$32,000 December 20. This is at the rate of 4c. per share. The mill is running steadily, treating 110 tons of ore per day, and it is understood that the company is to increase the capacity in the near future.

WHITE PINE COUNTY.

(Special Correspondence).—Five steam shovels are working at Copper Flat on the Nevada Consolidated, three stripping the ore, two loading it into the railway cars.—The new working shaft of Ely Central on the Eureka fraction is going down at the rate of 100 ft. per month. It is expected to cut the leached porphyry at a depth of 350 ft., and enter the sulphide near the 400-ft. point. Keystone drilling will be started 200 ft. south of the new shaft on the Eureka fraction, Quartette, and Weber claims.—The Giroux Consolidated has completed the drilling of a 1035-ft. hole on the Rickard claims reported to have been in ore the greater part of the way, with much native copper in the core. A second hole has been started and will be followed by a third. It is said that the hole cut a body of commercial copper 100 ft. thick at a depth of 800 ft.—Ely Consolidated has resumed work at two shafts and expects to commence early operations at the third.—Federal Ely is to resume work.—The shaft at the Boston-Ely has cut the sulphide ore and the management of the company is planning for more extensive development. Edward W. Ralph is superintendent.

Ely, December 11.

OREGON.

JOSEPHINE COUNTY.

Charles A. McKinnon, of Grants Pass, sold his group of claims in the Sucker Creek district to Max Kuhn for \$10,000. There are a number of rich properties in this district though no extensive mining has been done since early days.—A Pelton water-wheel and 3-drill compressor have been installed recently at the Oriole mine in the Galice district, and electric equipment will be added in the near future. Four drifts have been run on the vein and several shipments of the high-grade ore shipped to the Tacoma smelter.—I. J. Merrill, of Portland, has taken over the Big Four, formerly known as the Judson placer mine, on Pickett creek. The work at the mine will be in charge of C. D. Crane.—At the Mountain Lion mine, seven miles west of Murphy, the management is installing electric amalgamating apparatus in the 5-stamp mill. T. J. Brinkerhoff is superintendent.

UTAH.

JUAB COUNTY.

The stockholders of the Little Chief company have turned their stock over to the Chief Consolidated company at Tintic, and are now shareholders in the larger concern. The Chief Consolidated is now shipping six cars of rich silver ore per week.—The Black Jack mine, one of the Knight properties, at Mammoth, has been closed down temporarily. The Opohongo company which is operating through the Black Jack shaft will continue shipping, keeping the hoist and compressor running.—Two cars of zinc ore were shipped from the Scranton mine in North Tintic to the Bartlesville plant and lead ore is being sent to the American Smelting & Refining Co.—The Golden Chain Mining Co. has taken over the ground of the Ajax company in the Tintic district.—Operations have been suspended at No. 1 shaft of the Iron Blossom company on account of the unfavorable rate paid by the smelters for the low-grade copper-silver ore.—A 35-ft. cross-cut from the shaft on the 100-ft. level of the Grutli property opened a body of low-grade lead-silver ore.—Lessees at the Provo are opening

some good ore and have been assured by the management that they will be granted an extension of their lease which expires next March.

SUMMIT COUNTY.

The Little Bell company, operating in the Park City district, has declared a dividend of 5c. per share, payable December 22.

SALT LAKE COUNTY.

Jesse Knight and E. R. Woolley, of Salt Lake, have purchased the Taylor & Brunton sampler at Murray for \$250,000.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The New Republic Co. reports having started shipments of ore from the Tom Thumb mine, under lease from the Midget Gold Mining Co. The ore goes to the British Columbia Copper Co.'s smelter at Greenwood, British Columbia.—At the Lone Pine, the lessees are shipping to the smelters from 70 to 75 tons of ore per week, which assays about \$20 per ton.

Republic, December 9.

OKANOGAN COUNTY.

(Special Correspondence).—The Palmer Mountain Tunnel, Power & Development Co. has suspended work in driving the adit ahead, and placed a diamond-drill in the adit. A contract to bore 1000 ft. into the hill, the completion of which will give a depth of about 1700 ft. below the surface, has been let.—An option held by S. C. Emmons and S. S. Callahan on a group of five claims on Goat creek, in the Upper Methow country, for \$15,000, has been taken up. Three shafts and two adits on the property have each developed gold and copper-bearing ore of payable value.

Loomis, December 9.

SNOHOMISH COUNTY.

J. Edward Spurr has completed an examination of the Monte Cristo mine for the Guggenheim interests and it is understood that they will purchase the property and start the Everett smelter in the spring. The Monte Cristo mines were the main supply of arsenic ore to the smelter before the Monte Cristo Mines & Metals Co. suspended operations.—Only two cars of ore per month are being shipped from the Wayside mine at Granite Falls on account of the heavy flow of water found on the 850-ft. level which has been recently opened. The ore contains copper and gold, and has a gross value of about \$50 per ton.

STEVENS COUNTY.

(Special Correspondence).—An important discovery in the Chewelah district has been made in the main adit of the United Copper mine, 1800 ft. in from the portal, and at a vertical depth of 450 ft., where a body of high-grade copper ore 6 ft. wide has been found. Two machine drills are in operation. A new adit has been started and new living quarters for the miners are under construction.—Carbonate and sulphate copper ore have been found in the upper adit of the Amazon mine, 160 ft. in from the portal and at a vertical depth of 121 ft.—The main adit on the Windfall mine is in 634 ft., and a contract has been let for another 100 ft., with the expectation of tapping the vein before it is finished. A good quality of ore has been mined in the upper workings.—Against the hanging wall of an 8-ft. vein in the Snowstorm mine, in the Fish Creek district, the International Mining & Milling Co. has opened a 15-in. streak of chloride of silver ore from which samples give an average assay of 1200 oz. silver per ton.—A vein 62 ft. wide is being opened on the Slate Creek group of claims, by the Metaline Mines, Ltd. The company has let a contract to drive a 300-ft. adit.—The Oriole Mining & Milling Co. is installing a 6-drill compressor plant and will continue sinking the main shaft during the winter.—On the Gypsy group of claims, 12 miles northeast of Metaline, a 4-ft. streak of ore in a vein 150 ft. wide, is being explored. It assays about \$60 per ton in gold, silver, and copper.—An assessment of one mill per share has been levied by the Bornite Mining & Smelting Co.—The Germania Mining Co., operating near Deer Trail, has received concentrating machinery for its tungsten property and will install it im-

mediately. The mine has been closed several months, but operations will now be resumed.

Metaline, December 11.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Davenport Coal Co. has been organized to work the old property of the East Crows Nest Coal & Coke Co., seven miles east of Frank. It is said there are about 8,000,000 tons of bituminous coal available on the property.—At the Deep Mine, Ltd., the management is planning a 3-compartment 550-ft. raise, with stations, and drifts from them on the orebody.—A rich find of free-gold has been made on the old I. X. L. ground in the western part of the Rossland camp, by Brokenshire & Evans, the present lessees. The vein is 2 ft. wide.—The diamond-drills have cut some good looking ore in the Le Roi and driving is now being done to more fully develop the finds. On the Josie claim of the Le Roi No. 2, Ltd., the shaft will be sunk only another 50 ft., to the 1350-ft. level, when the work of opening the ore-shoots from the 950 downward will be started.—No shipments were made from the Oro Denoro property of the B. C. Copper Co. during the week, but the shipments from the Mother Lode were somewhat above average. The B. C. Copper Co. is holding over 1,500,000 lb. copper for higher prices.—The eighth and last big furnace at the Granby smelter was blown-in last week, completing the work of augmenting the eight furnaces begun early in the year. The capacity of the smelter was increased about 1000 tons per day thereby.—Diamond-drill exploration has been started on the Rawhide mine of the New Dominion Copper Co. This is the first work that has been done on the property since the old company closed down.—A 20-in. galena vein was cut in the Argo tunnel at Greenwood last week 260 ft. from the portal.—The Crescent mine-compressor plant is being moved to a point near the Phoenix-Greenwood adit and machine-drills will replace hand work in a couple of weeks.—A 10-ft. vein of ore containing gold, silver, and copper, assaying from \$15 to \$20 per ton, was opened in the shaft on the Tip Top last week.—Diamond-drilling is in progress on the Massett coal areas, Queen Charlotte island. The B. C. Amalgamated Coal Co. is behind this work.—At the Red Cliff mine, in the Portland Canal district, the compressor and power building has been completed.—The Big Casino group of 6 claims, adjoining the Red Cliff, was sold recently for \$75,000, 10% down.

Rossland, December 10.

ONTARIO.

One ton of ore per day is being shipped from the development work on the 250-ft. level of the Beaver mine in the Cobalt district, and it is the intention of the management to erect a new power plant.—Drifts driven on the No. 5

McKinley-Darragh Mine, Cobalt.

Lawson vein, on the 80-ft. level, have opened shoots with a high percentage of smaltite and a connection will be made with the No. 8 shaft.—Considerable interest is being shown in the Porcupine district and a number of sales have been recorded.—A dividend of 5% has been declared by the McKinley-Darragh-Savage Mines, Ltd.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. H. CURLE writes from Teheran.

F. LYNWOOD GARRISON is in San Francisco.

R. S. RAINSFORD has been in San Francisco.

RALPH ARNOLD was in San Francisco this week.

GEORGE G. DIXON has gone to Liberia, West Africa.

C. W. PURINGTON has returned to London from Siberia.

W. M. BREWER, of Vancouver, was at New York recently.

JAMES BROWN is at the Hotel Stewart in San Francisco.

DONALD F. CAMPBELL has returned to London from Germany.

C. ALGERNON MOREING has returned from the Black Sea region.

FREDERICK H. HATCH returns to London in December from Natal.

AUGUSTE MATHEZ has opened an office at 42 Broadway, New York.

A. McARTHUR JOHNSTON, of Johannesburg, is on a visit to England.

THEO. F. VAN WAGENEN has returned to Zacatecas, Mexico, from Colorado.

C. B. KINGSTON is returning to the Rand, after a visit to England and Canada.

GEORGE L. MACKENZIE, of London, passed through San Francisco this week.

J. POWER HUTCHINS is in London, on his return from the eastern coast of Siberia.

ALLAN GIBB, resident engineer for the Tanganyika Concessions, has arrived in London.

J. MORGAN CLEMENTS passed through San Francisco Thursday on his way to Mexico.

ROBERT LINTON has been appointed manager for the Sierra Mining Co., in Chihuahua, Mexico.

J. A. TAFF has resigned from the U. S. Geological Survey to take a position with the Southern Pacific.

HENRY M. LANCASTER, mining engineer, Wallace, Idaho, has been taking a trip to Pacific Coast points.

ERNEST A. HAGGOTT is making a business trip to Globe and points in Mohave and Yuma counties, Arizona.

JOHN P. COSGRO, southwestern representative of Allis-Chalmers Co., is in Chicago on a brief business trip.

P. C. JUES is making a trip through several of the Western States in the interest of the Union Iron Works Company.

FRED T. WILLIAMS, of Park City, Utah, was in San Francisco this week, returning from a wedding journey to Hawaii.

F. W. HARBORD has been engaged by the Transvaal Government to report on the coal and iron resources of the Transvaal.

THOMAS PASCOE, recently manager of the Mount Boppy mine, in New South Wales, has opened an office at 509 Salisbury House, London.

IRVING ANDERSON, of the engineering firm of G. Scott Anderson & Son, Wallace, Idaho, will soon visit the mining districts of western Nevada.

CLIFFORD WILFLEY has been appointed superintendent for the Virginia & Mexico Mine & Smelter Corporation in place of P. R. WHITMAN, resigned.

C. A. BOHN, for a number of years in the smelting department of the A. S. & R. Co. in Mexico, has changed over to the mining department of the same company and will be with S. W. Eccles, vice-president of the company, in New York.

THE San Francisco Section of the Mining and Metallurgical Society of America will meet at the Palace Hotel, San Francisco, at 6:30 p.m., December 20, instead of 15, as announced last week.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

HANDBOOK OF BRITISH GUIANA, 1909. Edited and compiled by George D. Bayley. Published under the authority of the Permanent Exhibitions' Committee. Dulau & Son, London; J. H. Stark, Boston, 1909. Price \$1.20.

An energetic publicity campaign is being conducted by the Crown Colony of British Guiana to attract settlers and capital. Recently we reviewed the handsome and interesting volume on the geology of that country published to that end. We now have before us a comprehensive handbook which affords a description of the country, its climate, geology, flora, fauna, and products, together with statistics covering every detail of industrial life. It is a volume of 607 pages, octavo, beautifully printed and illustrated with a map and many handsome photogravures. There is an interesting historical review by James Rodway, and a résumé of the geology by J. B. Harrison. With the agricultural resources we have little to do, though it may be said in passing that the opportunities seem to be exceedingly great, especially in the cultivation of cacao and rubber. The great obstacle to agricultural development has long been the want of labor. The effort of the Colony is to secure independent workers who shall own the land, to which end homesteads are limited to five acres. This seems excessively small, especially considering that nine-tenths of the total area of the country remains unappropriated. There is a hint, however, of extraordinary productive capacity of the soil involved in the small acreage of the homestead claims. The population is estimated at 304,000. The area is 690,000 square miles, and 147,851 acres is under cultivation. The climate is unusually healthful for the tropics, the death rate of 30 per 1000 being accounted for to a large extent by excessive infant mortality among the poor.

Mining activity cannot be considered great. The total recorded output of gold has been 251,801 oz., of which 45,462 has been yielded by quartz mines. The bulk of the remainder has come from crude washing of alluvial gravels, mostly with the long-tom. The Barima mine has yielded 7796 oz. gold, and is now erecting a mill of fairly large proportions. The Guiana Gold Concessions, Ltd., has a mill of 15 stamps, and in the last 3½ years has produced 28,549 oz. The Guiana Gold company has been operating a dredge for over two years on the Konawaruk river, a tributary of the Essequibo, and has turned out 6976 oz. gold within that period. It is now erecting a second dredge. The Handbook insists upon the possibilities of extensive dredgeable areas in the Colony. Prospecting licenses are issued at \$5 per year, giving the holder the right to locate any number of claims 1500 by 800 ft. Claims are held under a rental system of \$5 each per annum. No extralateral rights on veins are conceded. Exclusive prospecting permits for three-year periods are issued on payment of a fee of \$10, and a yearly tax of 7½c. per acre for the area embraced within the concession. Still larger areas may be taken up for prospecting on 99-year permits on payment of a nominal fee and a tax of 20c. per acre per year. Dredging concessions are granted in the same manner, on the payment of 10c. per acre yearly. A royalty is collected on all gold produced, amounting to 70c. per ounce. The full text of the mining law and regulations is given in the Handbook. Timber licenses may be obtained on areas not exceeding 2000 acres. A rental is collected amounting to \$5 for any area less than 500 acres, and \$10 for tracts of larger dimensions. In addition the Government collects a royalty on 'greenheart' or other hardwoods of 0.7c. per cu. ft. Other timber with a specific gravity of not more than 0.7 is subject to a royalty of 0.5c. per cubic foot, and firewood pays 8c. per cord.

A TREATISE ON MASONRY CONSTRUCTION. By Ira Osborn Baker. 8vo., pp. 762, tables, ill., index. John Wiley & Sons, New York, 1909. Price \$5.

The tenth edition of this standard work is before us, recast in all essentials for bringing it up abreast of the times.

The principal additions are in connection with concrete construction, as might naturally be expected. Mr. Baker's book contains a review of cement testing and mortars which makes it one of the best guides for cement users in existence. The subject of limes, cements, and concrete occupy 222 pages of the present treatise. On the engineering side the important new matter consists of a chapter on the elastic arch, that is, "one which is considered to support its load by virtue of the internal stresses developed in the material." Any voussoir arch, whether made of stone or brick, will act as an elastic arch as long as the line of resistance remains within the middle third of every joint, that is to say, as long as no tension is developed. Also any arch, whether voussoir or monolithic, will act as an elastic arch as long as the maximum tension does not exceed the safe tensile strength of the mortar or the elastic limit of the concrete. The author discusses the conditions for an arch having fixed ends, developing the subject mathematically, and he then considers the effect of temperature-changes, temperature-stresses, and stress due to shortening of arch-ring, followed by an exposition of the method of approximate solutions. Next comes a discussion of the reinforced concrete hingeless arch. In connection with this Mr. Baker succinctly epitomizes the advantages of reinforcing, in the following words. "Even though the economy in the use of steel in arches is not great, the reinforcement is practically of great value. Concrete is much more reliable in compression than in tension, and hence the use of steel to carry the tension adds to the reliability of the structure as a whole. Further, the steel is an economical insurance against uncertainties in the data, errors in the computations, shrinkage stresses, unequal settlement of the foundations, defective materials, and careless workmanship." An appendix contains specifications for cement and concrete work, and for railway masonry. Those who know this splendid work need not be told that it is free from padding. It is a plain useful engineering guide within the department indicated by its title. There is no other book which so adequately covers this field, and whatever Mr. Baker has written may be accepted as proved up to the limit of present knowledge. It is invaluable as a text-book and as a guide to the constructing engineer.

BENSON'S COMPENDIUM ON MINES, MINING, MINERALS, ORES, ROCKS, WEIGHTS OF METALS AND ROCKS; EFFECT OF HEAT ON VARIOUS SUBSTANCES, ETC. By H. T. Benson. Pp. 105, ill., index. Hall & Williams; Denver, 1909. Price, \$3.

Regarding the Silurian age, in that portion of the book devoted to geology, Mr. Benson says: "200 to 300 feet of drab-yellowish or light-gray thin bedded limestone of dolomitic; by some fossil shells it is recognized to be Silurian. Here may be found indications of lead, silver, or other ores, but not much gold as a rule." The rest is similar.

BIBLIOGRAPHY OF NORTH AMERICAN GEOLOGY FOR 1908. By J. M. Nickels, U. S. Geol. Surv. Bull. 409. Pp. 148. Washington, 1909.

This useful little bulletin is in continuation of the series so long compiled by F. B. Weeks.

WATER RESOURCES OF THE BLUE GRASS REGION, KENTUCKY. By G. C. Matson, with a chapter on the QUALITY OF THE WATERS, by Chase Palmer. U. S. Geol. Surv., Water-Supply Paper. Pp. 223, ill., index. Washington, 1909.

GEOLOGY AND UNDERGROUND WATERS OF SOUTH DAKOTA. By N. H. Darton. U. S. Geol. Surv., Water-Supply Paper. Pp. 227, figures, map, index. Washington, 1909.

PLEISTOCENE GEOLOGY OF THE LEADVILLE QUADRANGLE, COLORADO. By S. R. Capps, Jr., U. S. Geol. Surv., Bull. 386. Pp. 99, ill., map, index. Washington, 1909.

GEOLOGY OF THE LEWISTOWN COAL FIELD, MONTANA. By W. R. Calvert. U. S. Geol. Surv., Bull. 82. Ill., map, index. Washington, 1909.

GRANITES OF VERMONT. By T. Nelson Dale, U. S. Geol. Surv. Bull. 404. Pp. 138, ill., index. Washington, 1909.

Silver, Copper, Lead, and Zinc in the Central States in 1908.

The Geological Survey has just issued a report on the production of silver, copper, lead, and zinc in the Central States in 1908, prepared by B. S. Butler and C. E. Sieben-thal from statistics received from the mines. The States covered by the report are Arkansas, Illinois, Iowa, Kansas, Kentucky, Michigan, Oklahoma, and Wisconsin. The mines in this group of States report a decrease in the production of these metals from that of 1907 amounting in value to \$21,370,754, or more than 27%, the figures for the two years being \$77,697,457 and \$56,326,703, respectively. The most notable decrease was in the production of copper, which showed a loss of \$14,079,602, or more than 32%, the figures for 1907 and 1908 being \$43,553,466 and \$29,473,844. Michigan was the principal copper-mining State in this group in 1908, the other States mining chiefly lead and zinc. Most of the silver produced is derived from ores that carry mainly copper or lead. The loss in lead production in these States amounted to \$2,633,850, or 17%, principally in Missouri, the chief lead-mining and zinc-mining State in the country. Illinois, Iowa, Kansas, Kentucky, and Wisconsin, however, also show greatly diminished lead production. The lead product of the Central States in 1907 and 1908 amounted to \$15,516,174 and \$12,882,324. The loss in zinc production in this section—\$4,595,436, or 25%—was divided among three States, Kansas, Missouri, and Wisconsin. The figures for 1907 and 1908 are \$18,411,086 and \$13,815,650. Notwithstanding the general loss in the production of these metals in the central section, some States show gains in output of one or more of the metals. Missouri gained in silver, Oklahoma in lead, and Arkansas, Illinois, Iowa, and Oklahoma in zinc. The report contains charts showing graphically the average weekly prices of spelter and of standard zinc concentrate in 1907 and 1908 and the weekly production of zinc concentrate in the Joplin region during those years.

Commercial Paragraphs.

The GOULDS MFG. Co., Seneca Falls, New York, has been given the highest award for triplex power pumps by the directors of the Alaska-Yukon-Pacific Exposition.

THE LUNKENHEIMER Co., Cincinnati, Ohio, tendered its employees and families a Thanksgiving dance in one of its new factory buildings November 24. About 3000 people attended.

CHALMERS & WILLIAMS, Chicago, report that they have recently received orders for a 5-stamp cyanide plant from Byron E. Janes, Durango, Mexico; three 60 in. by 22 ft. tube-mills from the El Oro Mining & Railway Co., El Oro, Mexico; Burt cyanide filter and tube-mill from Swatling & Smith, Pearce, Arizona; forty 6-ft. Frue vanners from the Caucasus Copper Co., Russia; and a 25-stamp mill for the Republic of Colombia.

THE CYCLONE DRILL Co., Orrville, Ohio, reports the largest business for the month of November in the history of the company. There is unusual activity in the purchase of drilling outfits for all purposes. Among the shipments for the month are the following: five drilling machines for blast-hole work for the Panama Canal, six blast-hole drills for the Rio Tinto company for railroad construction in Spain, a core-drilling outfit for Hayti, and a prospecting machine for the Southern Development Company.

A change of much interest has just taken place in the F. M. DAVIS IRON WORKS, of Denver. The company has been entirely reorganized and re-capitalized. By this change John S. Cary becomes president, Robert J. Cary vice-president, L. C. Spaulding secretary and treasurer, and R. B. McConney general manager. Mr. McConney has been manager for several years of the Denver district for Allis-Chalmers Co. and has resigned to become associated with the reorganized F. M. DAVIS IRON WORKS. His wide acquaintance and experience will assure the success of the new company. Mr. Spaulding has been with the old organization many years, and he and Mr. McConney have purchased the interest of F. M. Davis. They will have the active management of the company.

Platinum Production in 1908.

Platinum is produced in the United States only as a by-product in placer-gold mining in Oregon and California. The output in 1908 was 750 troy ounces, valued at \$14,250. This quantity was nearly double that produced in 1907, but the value of the product was only about 35% greater, owing to a decline in prices. During the last three years the price of this rare metal has fluctuated from \$18.20 to \$38 per troy ounce for the refined metal (the value of gold is about \$20.67 per troy ounce), and the amount of crude platinum or platinum ore annually imported into the United States, chiefly from Russia, has ranged from 4237 lb., valued at \$1,095,754, to 11,494 lb., valued at \$3,601,120. The oldest uses of platinum were based on its resistance to chemical action and its high melting point, properties that made it valuable for use in chemical laboratories in the form of crucibles and other vessels. During recent years it has been used in jewelry, for it is probably the best material available for mounting diamonds, and also largely in dentistry. It is also used in electric lighting and heating and in making sparking plugs for explosion engines. The most important industrial use of platinum is found in the sulphuric-acid industry. More than half of the sulphuric acid now made is manufactured by the use of platinum. A report by David T. Day on the production of platinum in 1908, has just been issued by the United States Geological Survey. The pamphlet contains abstracts from a report by W. Geibel on the platinum deposits of Russia and the metallurgy and uses of the metal, an abstract of a report on platinum in Colombia, South America, made by Jay White, consul general at Bogotá, and a description of newly discovered deposits of platinum ore in Nevada, by Howland Bancroft.

Dividends.

American Smelting & Refining Co., December 1, declared a regular quarterly dividend of 1¼% on the preferred stock, and 1% on the common stock.

United Verde Copper Co. paid, December 1, the usual monthly dividend of 75c. per share, making \$9 paid this year compared with \$6.75 in 1908.

The Federal M. & S. Co. paid \$210,000 on December 15, at the rate of 1¼c. per share on its preferred stock. This makes \$930,000 for the year, \$90,000 being paid on common stock.

The Tennessee Copper Co. resumed payment of dividends November 24 by the declaration of \$1.25 per share. More than a year has elapsed since the last payment was made, \$1.25 per share having been distributed in September, 1908.

The Old Dominion Copper M. & S. Co. (New Jersey company) has declared dividend No. 6 of \$1 per share, the same as three months ago, payable January 3 to stock of record December 14. The directors of the Old Dominion Co., of Malne, met in New York December 2, and declared a regular quarterly dividend (No. 8), of 50c. per share, payable January 4, to stock of record December 14.

Catalogues Received.

LIDGERWOOD MFG. Co., New York. Bulletin No. 7. 'Electric Mine Hoists.' Illustrated. 9 by 12 inches. 20 pages.

THE ATLAS CAR & MFG. Co., Cleveland, Ohio. Bulletin No. 1090. 'Electric Locomotives, Trucks, and Cars.' Illustrated. 6 by 9½ inches. 52 pages.

THE SLIMES TREATMENT Co., LTD., Box 1094. Nelson, British Columbia. Bulletin No. 1. 'The Natural Settlement Method of De-watering and Recovery of Cyanide Solution from Slime-Pulp.' Illustrated. 8 by 10½ inches. 12 pages.

JAMES BEGGS & Co., 109 Liberty street, New York. Catalogue No. 35, 'Feed Water Filtration.' A treatise on the removal of organic matter, sediment, lubricating oils, etc., from the boiler feed water in power plants, and on the removal of any matter in mechanical suspension in liquids. Illustrated. 6 by 9 inches. 32 pages.

EDITORIAL.

DIVIDENDS by the Bunker Hill mine in Amador county, California, have been augmented by a Christmas distribution. The statement in our news columns last week gave a wrong impression which we are pleased to correct.

CHINA has a duly accredited minister from the United States. Mr. W. J. Calhoun is in every way qualified for the place and will make a most excellent representative at Peking. His peculiar fitness was, however, only discovered by the politicians who control appointments in Illinois, on his making a striking speech of welcome to Mr. A. B. Cummings. The possibility of his leading the 'Insurgent' forces in Illinois was too great to be risked. The need for Mr. Calhoun at home is the only disturbing thought in connection with his appointment.

GERMANY is to hold an International Congress of Mining and related subjects in 1910. The meeting will be at Düsseldorf, June 20 to 23, and the program is to include discussions on mining, metallurgy, applied mechanics, and practical geology. Americans are cordially invited to take part. Particulars may be learned from Dr. Schrödter, secretary of the Verein Deutscher Eisenhüttenleute, or Bergassessor Loewenstein, secretary of the Verein für die Bergbaulichen Interessen im Oberbergamtsbezirk Dortmund.

ELECTRIFICATION of the mountain division of the Southern Pacific railroad between California and Nevada is to be immediately undertaken. Electric locomotives of larger size than any now in use will be employed. The length of road to be electrically operated is 135 miles, and the change will involve an expenditure of nearly \$4,000,000. A few more such enterprises would have a most beneficial effect on the copper market. Apparently the electrification of railroads will henceforward proceed with great rapidity, both East and West.

REPORTS of a great dredging enterprise on the Feather river, to recover gold, reclaim large areas of land for agricultural use, and in the end leave the river navigable twenty-five miles above Yuba City, are all too good to be true. We would like to believe it, but the general understanding is that a short distance below Oroville the river gravels drop off suddenly in value to five cents and less per cubic yard. The new corporation, which would serve so many beneficent purposes all at once, is incorporated in Arizona under the title of the Feather River Dredging & Concentrating Company. The announcement is made that suction dredges will be

used. The project bears the ear-marks of inexperience.

OCTAVO folios are the latest, the United States Geological Survey having begun to publish a field edition of the 'folios' of the Geologic Atlas, in the smaller size. This raises some question as to when a folio is not a folio, but the old name is probably too firmly fixed to be disturbed. The new form of publication will be welcomed by mining engineers and will greatly increase the usefulness of the maps of the Survey. Books 18 by 21 inches in size are not well adapted to carriage on horse-back and to frequent use in field. Any one who has tried to control a horse with one hand while reading from a folio held in the other, perhaps with rain falling and wind blowing, will welcome the new octavo folios, regardless of linguistic complications.

THIRTY YEARS of service as editor is a long period, particularly when the years have been spent in the service of one paper. Mr. Charles Kirchhoff, who retired this month from the position of managing editor of *The Iron Age* after such a term, has seen that paper grow mightily in wealth and influence, and he has contributed notably to its success. He has found time also for much good work aside from his editorial duties. His reports on lead, spelter, and copper, made for many years to the United States Geological Survey, are models of accuracy and fairness. In that they reflect the spirit of their author, a spirit which he, with the aid of his associates, breathed into our distinguished New York contemporary. To it and to Mr. Kirchhoff we extend not only the compliments of the season, but our good wishes for all time.

Christmas 1909.

Christmas is here, but whose stocking contains the profits from our 'lower' tariff is still under debate. At one time it seemed as if stockings themselves might be taxed out of use, but Mr. Cannon and Mr. Aldrich, perhaps with a vivid recollection of certain features of the Populist movement, got together and agreed to lower the proposed figures. The stockings are here, but some, alas, are empty. Zelaya is still looking for the dove of peace and a chance to spend in quiet the simple savings of a plucky life. Dr. Cook is looking for a less suspicious public, while Mr. Peary is looking for Dr. Cook. Mr. Hammond's stocking contains no vice-presidency this morning, and Mr. Ballinger's gapes for a vindication which won't rub off. It is currently reported, on the other hand, that Mr. Pinchot has a brand-new history of France and is re-reading the chapter on the return from Elba. Mr. S. F. Emmons has a whole stocking full of honorary degrees, while Mr. W. A. Caldecott and Mr. William Gowland each found a well deserved medal hidden down toward the toe. The Geological Survey, thanks to the unexplained opposition of Mr. J. R. Mann, has not received that new building whose angular corners it was hoped might by this time be seen distending the elastic lisle thread. The American Mining Congress is still hoping for that aid in getting a Bureau of Mines, which Santa

Claus Taft led it to expect. The American Institute of Mining Engineers had hoped for a stocking full of contributions to its funded debt. The Mining and Metallurgical Society had one stocking spread for a policy, and the other for a leader who could overcome inertia in the mass of its members. State geological surveys everywhere will doubtless leave their stocking pinned conspicuously to the mantel till the last legislator goes home, and the 'Copper Combine' will hope against hope, for a few days at least, that the congested condition of the mails accounts for the non-delivery of the package containing Government approval of its plans. The United States Steel Corporation is duly thankful for orders received and its stockholders for dividends paid. Many other stockholders have needed to hang only the baby's stocking this year, and yet there are notable exceptions. On the whole, 1909 has turned out better than was anticipated. The splendid record of the Goldfield Consolidated, to mention only one of the many, has enabled nearly five million dollars to find its way into various stockings. Many mining engineers who received from their clients nothing but Christmas cards bearing fine sentiments last year, have been better remembered this time and are appropriately cheerful. A general and welcome Christmas spirit is in the air.

Leasehold System for Mineral Lands.

Withdrawal of the phosphate lands from location until their character as lode or placer deposits might be determined has resulted in the introduction of a bill by Mr. Reed Smoot intended to unlock these valuable resources to normal development. The bill represents a frank concession to the principle of the leasehold, which has been advocated energetically by a growing number in what we might call appropriately the Conservationist Party. It is interesting in this connection to note that the leasehold formerly constituted the sole means by which mining land might be acquired and held on the public domain of the United States. After trying this for awhile in the lands acquired from Mexico, the American, with his instinctive love for independence, demanded that protection of his title which comes through patent. A leasehold is a grant, which accords a vastly lower order of possession than ownership in fee simple. The latter is a right which is not defeasible. To be sure, the failure to pay taxes works forfeiture to the State after due process of law. This has been likened to the royalty or rent payable as a condition for leasehold rights, but the difference is wide and deep. All claim to a leased property ceases and determines, as the lawyers say, immediately that the time of payment has passed, if the money has not been paid. We recall the case of a certain famous mine in Mexico which was stolen from its owners by the general manager, who craftily let the time for annual rental go by unheeded, but was not so careless in regard to re-denouncement. A fee-simple title, however, in a certain sense attaches the soil to the man. Only a decree of court can quiet title as against a former owner; failure to perform all the acts specified by law does not inherently cause instant sacrifice of his rights. There may be reasons

why a man cannot perform all that is required by law; the relations of rightful owners are sometimes so complex that the courts must determine the validity of respective rights and obligations.

It is needless to re-argue the matter at length, but we could safely predict that the world would be shaken with agrarian protests should it be seriously proposed to change patented rights in agricultural lands to the flimsier possessory form of leaseholds. It is questionable whether such substantial development would occur in a community holding property under a system of short-time leases, whether the owner be a land-baron or a national government. Examples are many. Historic in America is the feeble development of the vast Helderberg estate in New York until after the 'Van Rensselaer Rebellion' which compelled the granting of titles to the determined farmers. The relatively unimproved condition of the great ranches in the Southwest, where the work is done by tenants, on short time leases, as compared with areas split up among numerous owners, affords many a startling contrast. If it be objected that such tenants are liable to fluctuating rental, it may be said that the possibility of a change is present under a leasehold system, even when the grant issues from the Government, though it is customary for such changes to be made at times and in ways provided in the lease. These phases of the question appeared so important to the early miners of the West that the demand for ownership in fee-simple became one of the strong arguments which hastened the passage of a mining law providing for the disposal of the public mineral lands. It was one of the incentives which impelled John Sherman to draft the measure from which has come the fundamental mining law of the land. The force of the contention of the miners for substantial property which they might securely hold, or convey as other property is conveyed, appealed to the sense of justice in the hard-headed legislator, who saw financial advantages for the Government as well, in the proposed alienation of public lands.

As opposed to the view which prevailed when the mining law was enacted, a plausible argument is advanced. It is an argument which appeals primarily to that part of the population not directly interested in the exploitation of the classes of mineral land involved in the proposed changes. Instead of a flat-rate of so much per acre, the income would be proportioned to the assessed value of the property, as determined by its actual mineral content, and its natural advantages for exploitation. To some extent this principle has long been operative in relation to coal lands in the West. If the prime purpose in the administration of the public land be to gain as large a revenue as possible for the Government then the leasehold system offers a certain method for swelling the exchequer. If the public lands are to be utilized to reduce taxation for the maintenance of the Federal Government, and the 'people in congress assembled' do so enact, nothing remains to be said. It has been a settled conviction, however, that one part of the country should not be taxed for the benefit of another part, and the man in Idaho or Utah, paying generous royalties on phosphate lands

to help reduce the taxes for the wheat-grower in the Red River valley of Minnesota, and for the potato-grower of Maine, would likely feel that a certain injustice had been done in the expansion of this idea of public ownership.

There is no doubt, on the other hand, that such a system is a check upon private monopoly. It renders the locking up of large areas of mineral land economically impossible. It limits the absorption of holdings to those that can be utilized within a reasonable time. The same end could only be attained by appraisal of the lands in accord with their varying worth, and issuing patent to competent locators on application. It is with a view to control of monopoly that the movement for a leasehold system has arisen. Greed of corporations in the control of natural resources has become a peril so great that we join heartily in commending those faithful Government servants who would protect the rights of the whole people against infringement by a few. It is the proposition to depart from secure tenure in fee simple to the less firm right involved in a leasehold that makes one question whether it be wise. Mr. Smoot has given a new turn to the matter by introducing such a principle into the bill for taking up phosphate lands. If the system be extended from one mineral to another it is logical to suppose that it will ultimately be applied to all.

The leasehold system prevails over the larger part of the world; the majority is therefore against us. America, however, has until lately been a land where the individual right has been always exalted, and where the tendency toward strong centralization has been resisted. The leasing of public lands is one more expression of centralization, a tying of the man and the land more closely to the sovereign power. It takes from the pioneer the opportunity to absorb the unearned increment, except to the extent that is provided in his lease. We have seen how the prospector in the wilds of northern Ontario has had his chances of fortune lessened by a withdrawal of surrounding territory for re-appraisal as soon as announcement of his discoveries was made through filing on the land. The same thing occurred in this country when the phosphate lands were withdrawn from entry. We have protested against this, as any form of impairment of legal rights is abhorrent to Americans.

The question is many-sided, and there are many interests to be considered. The public is bigger than the individual, but that does not necessarily make its interest more vital. The public is but an aggregate of individuals, and in modifying the right of one, the rights of all are affected. Individual initiative is too valuable a national asset to be seriously jeopardized. The leasehold system has its dangers, and careful search should be made for a way to protect the national resources and prevent monopoly before calling back a system of land-tenure which has so long been alien to our thought and practice. The case of oil, which involves a substance which cannot be retained within territorial boundaries, is different. There the principle of leasing appears to insure as great justice to the proprietor as ownership in fee-simple.

MINING METHODS AND COSTS AT THE
ESPERANZA MINE.

Written for the MINING AND SCIENTIFIC PRESS
By W. E. HINDRY.

Ore breaking in the Esperanza mine was carried on under varying conditions as regards size of stopes and character of material broken. In the early days of the mine, the hanging wall portion of the San Rafael vein in the section south of the fault was worked and this was by all odds the most stable portion of the mine and value of the ore comparatively uniform. The stopes here varied from 6 to 40 ft. in width, with an average of some 25 ft. and the assay values were quite sharply defined between the shale hanging wall on one side and a zone of hard 'bull quartz' or a 'horse' of slate on the other. The lengths of the stopes on the various levels ran from 100 to 600 ft., this last being the greatest length of any single ore-shoot so far opened. North of the fault the ore masses were irregular, the width across the vein being at times greater than the length, as shown along the strike. The distribution of the gold was also very erratic. Some of these stopes had, at points where the vein swelled out, a width of 175 ft. and elsewhere narrowed down to 5 ft. In all cases the ground was excessively 'heavy' due to the fact that the calcium content of the shales oxidized or 'slaked' upon exposure to the air, with the result that a crushing force was exerted that no amount of timber could support. This was especially true of the ground north of the main fault where the vein itself was more shattered and less stable than in the south section.

The following is a statement of costs per wet metric ton of ore-breaking for several years, from which an idea can be formed of the expense attached to the various operations.

| | Ore production. | | Cost per ton. | |
|-----------------------------|-----------------|---------|---------------|---------|
| | 1904. | 1905. | 1906. | 1907. |
| Wet metric tons broken..... | 134,620 | 192,004 | 217,514 | 167,708 |
| Drilling: labor | \$1.58 | \$1.48 | \$1.75 | \$1.78 |

| Mine to mine bins..... | 1.14 | 1.07 | 1.33 | 1.34 |

NOTE.—'Mine to mine bins' as given above is made up of costs of tramming and hoisting, these in turn including costs of labor, power maintenance, and so forth.

All stoping was done 'overhand' and at first square sets of 10 by 10 in. timber were used. It was found, however, that it would be impossible to hold the ground open for any distance in height without filling and therefore the size of the timbers used was reduced to 8 by 8 in., the sets being filled with waste immediately after the ore was removed. In the more solid portion of the vein in the south section it was found possible to mine considerable ore without the use of any timbers whatever, the ore being taken out in sections of 100 ft. in length along the vein. The 'cut' or slab of ore broken was some 15 ft. in height and it was shot down after drilling by machines. In this manner one 100-ft. section would be in process of being drilled preparatory to shooting; along a second the ore would be being removed, while a third was being filled with waste material.

As a result of the decomposition of the shale walls, a large amount of heat was evolved. In certain sections of the mine, even where the air circulation was free, stopes and drifts became excessively hot, and in the event of a stoppage of the air-current for even a short time, the heat became almost unbearable. Artificial ventilation had to be resorted to in many instances in order to enable the men to work.

In a general way, the scheme followed in the blocking out and handling of the ore was the same in all cases. Drifts were driven, usually in the foot-wall quartz, more or less parallel to the orebody to be mined. From these drifts cross-cuts were driven through the orebody; in the south section at intervals of 50 ft. This in the north section was subsequently increased to 20 m. From these cross-cuts, raises were put up on the foot-wall side of the orebody, outside of the ore itself, from level to level. These raises were of two compartments, one being used as manway and the other for handling both ore and waste, the waste coming into the stope from above while the ore was passed through the lower portion of the chute.

After completion of the raises and cross-cuts, the sill floor of the stope was broken out by driving a face the full width of the orebody from cross-cut to cross-cut, this being timbered with square sets as progress was made. In the meantime, at points opposite the raises, the first, second, and sometimes the third floors were also being opened, it being the general idea to keep the floors opposite the chutes opened to a higher level than the balance of the stope in order to facilitate the handling of the filling material. Where the stopes were unusually wide, chutes for the extraction of the ore were carried up with the stope and raises were driven from convenient points to be used as 'mill holes' for the handling of filling material from above. The 'waste' or barren material for the filling of the stopes was derived from various sources including: (1) the waste broken in development headings; (2) as the waste is not sufficient for the demand, waste from caving stations; and (3) when the case was urgent and no other waste material was immediately available, cross-cuts were driven into the hanging wall or foot-wall. The endeavor was usually made to drive these waste cross-cuts in such a manner that

they would serve as exploratory work in addition to the securing of filling material.

The caving stations were formed by driving cross-cuts or drifts in suitable places, where the caving of the ground would not affect any of the workings, to a considerable distance away from the vein. At the end of these cross-cuts a chamber was cut out and the ground allowed to cave, after which the only expense attached to the securing of the material was the cost of loading and tramping.

A standard square set was adopted, the timbers used being square sawed timber, 8 by 8 in., framed with the view to affording the greatest resistance to strains in the direction from which they usually came. The sets were 5 ft. square, centre to centre, and 7 ft. 6 in. high, also centre to centre. They were not designed as a permanent support for the ground, but simply to prevent any sudden movement while the ore was being removed. Not more than one floor was open at any one time, and it was rare that even this was true. The ground was so heavy that immediate filling was necessary in order to prevent serious accidents and as a rule, the filling followed close behind the breast where the ore was being

ground in the neighborhood of these west veins was heavier and harder to handle than that adjoining the main San Rafael vein, the result being that great difficulty was experienced in holding the main drifts open. Various expedients were tried in this connection, the final result being that the drifts were timbered with sets made of 14 by 14 in. timber, outside of which were placed 10 by 14 in. posts and caps with a block of 6 in. between the main and auxiliary sets. This permitted the 'easing' of the outer timbers and the lagging without greatly interfering with traffic, but even with this method, the frequent re-timbering of the drifts was necessary. The heat evolved from the decomposition of the shale walls was excessive and great difficulty was experienced in keeping the temperature of the stopes down to a point which permitted men to work. Where the natural circulation of air was not strong, artificial means had to be adopted, exhaust or pressure blowers driven by electric motors being used.

Three classes of ore were broken and handled, namely: shipping ores, sulphide milling ores, and oxidized milling ores. The first two mentioned were derived from the west veins, with the exception of

Esperanza Mine and Mill.

broken. Two-inch planking was used for flooring of the sets next to the ore breasts, this planking being removed prior to filling. No attempt was made to recover any of the timber of the sets themselves. Where necessary, gangways were left open, usually only for a short time. These were formed by lagging a row of square sets with 2-in. plank and filling in behind them. Chutes and 'mill holes' in the body of the stope were cribbed with 8 by 8 in. timbers, as were also the majority of the raises on the foot-wall, these being made in two compartments, each independent of the other in order that one side might be repaired while the other was in use. Where the ground was exceptionally heavy lagging was driven, but as a rule, this was not necessary. When occasion arose for quick action, solid cribs were built in the stopes for the strengthening of some particularly weak place. These cribs were built of square timbers—usually old timber derived from the renewal of drift sets, or shaft sets.

In the breaking of the ore from the west veins, which were relatively narrow, an attempt was made to use stulls and filling rather than square sets and filling, in order to reduce the timber costs. This was a failure and square sets were afterward used. The

a small quantity which was mined from the foot-wall body of the San Rafael vein on the levels 7 and 8. The oxidized milling ores or third class, formed the bulk of the production as regards tonnage, and were derived from the large orebodies of the San Rafael vein. The distribution of gold in the veins was erratic, more especially in the stopes north of the main Esperanza fault. This necessitated taking a large number of samples daily—from 300 to 400—and special gangs of men were employed in this work. A system of numbering the various raises and cross-cuts, was adopted. The numbers formed the basis of another system applied to the stopes, every square set being designated by its proper number, the result being that an exceptionally comprehensive system of assay plans and maps was evolved and kept up-to-date. The relation of the gold to the silver in the various parts of the mine was relatively constant so that assays were made for gold alone and the calculation regarding the lowest grade of ore to be broken based thereon. For the convenience of the shift-bosses and foremen, as well as the management, all assays were marked up in grams per metric ton at the points from which they were taken, these marks being made on the

mine timbers with a composition of kerosene and lamp black and corresponding exactly with the assays marked on the maps and plans kept in the drafting office. By means of these assay plans it was possible at any time to make up a very close estimate of ores in sight in the mine or any portion thereof, and in giving instructions to the mine foremen the grade of ore to be broken and portion of the mine from which it was to come, could be exactly specified.

It was a common occurrence to find a considerable variation in assays taken from the same point, this being due, not to improper sampling or assaying, but to the erratic distribution of the gold and silver in the quartz. In case there was a doubt as to whether the portion of the stope where this occurred was above or below the payable limit, the broken ore was left in the stope until the pile could be thoroughly sampled. Inasmuch as there were usually a number of these doubtful piles at various points throughout the stopes, they were designated by the position in which they lay, as regards number of the set, and when their value had been determined, were either delivered to the chutes as ore or thrown back as waste.

In breaking the ore in the stopes, drilling was done both by hand and machine, practically all work being done by contract at so much per set or cubic metre of ground broken and delivered to the chutes. The machines used were Ingersoll-Sergeant 'baby' drills and air-hammer drills, using $\frac{7}{8}$ or 1-in. steel. Hand-drilling was usually double-hand work, the steel used being $\frac{7}{8}$ in. The air-pressure carried was from 90 to 100 lb. per sq. in., and pipe lines were carried up the foot-wall raises and the air distributed to the various points of the stopes. The pipe lines in the raises were usually $1\frac{1}{2}$ or 2 in., and the distribution lines 1 in. The explosive used was 60% dynamite, fired by fuse and caps in all stope work, the fuse for comparatively dry places being 'double tape,' and where very wet 'triple tape.' The detonators or caps were in all cases quintuple strength, it being found that superior results were obtained by this method as compared with detonators of lower strength. Timber was placed by contract, either at so much per piece or per set, as the case might be, an average price for stope work being \$1 per set, which included blocking and lagging. Where it became necessary to reinforce, renew, or place extra timber or cribs, the work was handled at so much per piece.

The lighting of the stopes was done with candles, although all drifts were illuminated by electricity. The handling of the ore from the breasts to the chutes was by means of wheelbarrows or small stope cars of 16 cu. ft. capacity, where the distance was too great for economical handling by shovel, and these same wheelbarrows and cars were used in the distribution of filling material to points where it could not be delivered direct by gravity. From the chutes the ore was trammed to the shafts, both by hand and electric locomotive, the latter being used for long hauls. At the shafts the ores were either dumped into 'pockets' and from these drawn off into cars standing on the cages, after the manner of loading skips, or what was more usual, run direct-

ly onto the cages and hoisted to the surface. In loading the cages at the various stations, one deck was filled at a time, but on the surface both decks were unloaded and empty cars run on to the cages simultaneously. The first-class ore from the west veins was kept separate in the stopes and when hoisted to the surface was run direct to the sorting house preparatory to shipment to the smelter. The milling ores, both second and third class, were delivered to grizzlies from which the fine product passed directly to the large underground bins situated at both shafts, while the coarser material was crushed by means of 13 by 24-in. Blake crushers to suitable size for treatment by Huntington mills or stamps, the grizzly for the Huntingtons having an opening of $\frac{3}{4}$ in. between bars while that for the stamps had $1\frac{1}{4}$ -in. openings.

Average assays and analyses of the various ores broken, were as follows:

| | First class. | Second class. | Third class. |
|--|-----------------|------------------|-----------------|
| Dry tons sampled..... | 10,430 | 35,127 | 37,113 |
| Au grams per metric ton.... | 84.30 | 51.70 | 15.40 |
| Ag grams per metric ton.... | 875.00 | 505.00 | 97.00 |
| As % | 0.40 | | |
| Sb % | 0.25 | | |
| S % | 1.20 | 1.54 | 0.25 |
| Insoluble % | 89.00 | 84.70 | 92.80 |
| SiO ₂ % | 84.50 | 77.60 | 86.10 |
| Fe % | 2.70 | 2.30 | 1.30 |
| Mn % | | 0.10 | Trace |
| CaO % | 3.30 | 5.90 | 2.40 |
| MgO % | 0.20 | 0.40 | Trace |
| Al ₂ O ₃ % | 1.80 | 6.30 | 5.90 |
| CO ₂ % | 2.60 | 4.63 | 1.88 |

The tonnages given at the head of each column denote the amount of ore from which the average samples were taken, the samples being aliquot parts of smelter pulps and daily mill samples and therefore representing a correct average of the tonnage sampled. No lead, copper, fluorspar, or bismuth was found in the ore. A trace of zinc was present in the second and third class.

The timber consumption in the mine was, as might be expected from the nature of the ground, unusually heavy. The total consumption of timber as used for all purposes underground, is given in the following statement:

| | 1904. | 1905. | 1906. | 1907. |
|---|-----------|-----------|-----------|-----------|
| Total board feet consumed | 3,997,649 | 7,595,726 | 8,906,552 | 5,904,188 |
| Board feet consumed per ton ore broken | 29.70 | 39.56 | 40.27 | 35.20 |

In 1904 only the ores of the San Rafael vein were mined, while during subsequent years the west vein ores were also broken. All square sets and chute cribbings were framed by machine, the cost being as follows: girts, \$0.0687; caps, \$0.0890; cribbing, \$0.0569, each. Other timbers such as drift sets, shaft sets, raise and winze sets, were framed by hand, this being done by native contractors so much per set. It is interesting to note that in comparing hand with machine work on the framing of cribbing, the best price at which this could be done by hand was \$0.10 each as against the \$0.0569 for machine as above given.

DAVIS CONSOLIDATED HYDRAULIC MINE.

The old Van Brunt mine, of approximately 1200 acres along the Klamath river in the Happy Camp basin in Siskiyou county, was recently purchased at a sheriff's sale by Reeves Davis, of San Francisco, who has re-christened it the Davis Consolidated mine. The property is interesting historically, as it is one of the oldest mines in the State, and its rejuvenation will mean much for Happy Camp. The sale included a number of buildings at the mine all in good repair, a saw mill, hydraulic equipment, with several miles of flume and a dam, which were damaged by the high water two years ago, and a number of water rights. The property, a portion of which is shown in the accompanying photograph, has been operated since 1852 under different companies, the last being the Oregon Gold Mining & Water Power Co., which was controlled by O. H. P. Belmont, and the firm of Coster, Knapp & Co. Owing to the death of Mr. Belmont

WHAT SHOULD AN ENGINEER KNOW OF LAW?

By COURTENAY DE KALB.

*A certain acquaintance with legal principles is a necessary part of a liberal education. Every man should know something of the common law, and of the civil law, which is the law of Rome. These are fundamental. Our civilization is built upon them; unconsciously we think in terms of them through the experience we acquire in the practical affairs of life, but our conceptions are crude and lead to false reasoning unless we have studied systematically. It is never safe to trust to general impressions. The common law, which is the crystallization by statutes and judicial decisions of previously established custom, deals with the primal relations between man and man. It represents the accumulated experience of the world in those adjustments of right and privilege which render possible the existence of human beings in a state of association. It is the basis of the

Part of Old Workings at Davis Consolidated Mine. Gravel Bank 170 ft. High.

and the failure of Coster, Knapp & Co., operations were suspended at the mine. November 19 it was sold to satisfy a judgment of \$80,910, the plaintiff being William De Long, of New York.

The gravel bank averages 100 ft. in height and 1800 ft. across. Only a portion has been worked. Samples taken from an adit driven 400 ft. along the bedrock, showed the gold content of that portion of the gravel to be high, and the 60-acre tract farther west has been thoroughly tested by Robert B. Stanton with a Keystone drill. It is estimated that the clean-ups of the former operators amounted to \$11,000 per acre, the mine being credited with a production of \$400,000 from 1852 to 1888, \$110,000 from 1888 to 1899, and \$200,000 from 1899 to 1906. There is ample room for disposal of the tailing as the sluices empty 85 ft. above the level of the Klamath river.

With the renewed activity in hydraulic operations at Happy Camp and the representatives of a number of companies examining copper properties in the neighborhood, the district seems to be in a fair way to again become one of the prosperous mining communities of the State.

social contract. Reduced to its simplest terms the common law establishes the bases for determination of rights and duties in regard to possession and ownership, contracts, torts or injuries, and inheritance. No man can know the law of the land in relation to any of these things by a study of the common law, for legislation is eternally changing, but certain fundamental conceptions underlie all the mass of law that has accumulated, and these conceptions cannot be arrived at by inspiration.

Advancing beyond these elements the man in charge of affairs needs a considerable amount of special knowledge. He is usually acting in a capacity which is recognized in law as that of an agent. He should know the legal limits of his authority, his duties and liabilities, his rights and privileges; he needs to know how far he can bind his principals; when he has made a binding contract for them; how he may enter into engagements which he can defend by action in court which he is capable of bringing; how far acquiescence in his acts commits his principals. The work of a mining engineer involves

*Abstract of an address delivered before the Students' Mining Association, University of California.

a multitude of complicated functions; he is perpetually entering into agreements less formal than contracts, and he needs to know the force and probable consequence of such agreements; he is called upon to make assignments, and to obtain assignments from others; he must be grounded in the law relating to damages, where the instinct to resent aggression is likely to blind his judgment. It is not easy for a layman to appreciate the significance of the principle that there is no right to damages where there is no wrong, and that an obligation violated must be one owed to the party claiming to be injured. An understanding of the principles underlying a legal basis for an action to recover damages will go far toward keeping the blood cool under vexatious circumstances. Hot-headed reprisals which seem justified by common conceptions of equity, may cause the loss of legal advantage, and work injury to a man's employers.

The control of labor soon brings the engineer face to face with problems involving conspiracy, with injunctions, and the protection of property. Newspaper law will not help a man in these affairs, and while he would appeal to a lawyer for advice if time allowed, it often happens that he must act quickly, with emphasis and accuracy. Experience is a slow and costly teacher. The man who depends upon learning how and what to do in the ordinary affairs where the law is concerned as each case presents itself, is sure to look back regretfully upon many errors. How to obtain this knowledge, is something each man must determine for himself. The crowded curriculum of a university leaves no room for a legal course of study in conjunction with technology, and a few lectures can do no more than give a little inspiration. The young man on leaving college should make good this deficiency in his training by systematic application. In the first few years of his practice he has more leisure time than he will ever have again. He is apt to think he is egregiously busy, but he really is not as busy as he thinks. There are many useful works which would serve for the elementary legal training which an engineer could obtain by private study, but I would suggest Robinson's *Elementary Law*, Pomeroy's *Municipal Law*, and Holland's *Jurisprudence*. Holmes' *Common Law* and Muirhead's *Law of Rome* might also be included. Then if one wish to go deeper he might read Kent's *Commentaries*, and finally put Bouvier's *Law Dictionary* on his shelf as a work of ready reference, along with Parson's *Laws of Business*. Another way to acquire an elementary legal training is to take a course in a Correspondence School of Law. In two years, with moderate work in the evenings, a bright student can complete a course which would suffice to admit him to the bar if he so desired. Such work makes for strength and efficiency, and can be done while a man is young without sacrifice of technical reading.

I have chosen to emphasize first the need of acquaintance with general law, because even the mining engineer will find that a hundred general problems will arise to one in which his knowledge of mining law is called into service. A great body of special law has grown around mines, and the subject

has many difficulties. The briefest treatise on the law of mines which may be accepted as standard is a recent work by George P. Costigan. Lindley's masterly compendium is out of print, but a new edition will be ready within a year. Costigan answers the questions which will concern the engineer, and the careful study of this volume will give him a firm foundation.

When a manager takes charge of a property, if he be wise his first concern will be to study the mine. There is usually something wrong there, which needs righting. After the underground situation is well in hand, and the geology of the deposit has been investigated, the rights under location of claims need to be studied. Then comes the struggle with the so-called law of the apex. Claims are usually located by men ignorant both of geology and law. Theoretically a claim should have parallel end-lines, crossing the lode, which latter should extend from end to end approximately through the middle of the claim. Then the owner may follow the lode or vein on all its dips, angles, and spurs beyond the limits of the claim, confined only between two vertical planes, containing the respective end-lines. This is the extralateral right, the most profound variation from the old common law right in real estate ever made. It has given rise to endless controversy, and often produces situations difficult to adjust by the combined wisdom of geologists and judges. In order to know what rights are controlled between the end-lines of one claim it is needful to study the position of the end-lines of adjacent claims which may have been located at an earlier date. For example, if the end-lines of claim *A* are at right angles to a straight lode, central with reference to the side-lines of the claim, and the lode dips at an angle of 45°, the sheet of ore on the dip lying within the end-planes would be traversed at no great depth by the extralateral possessory-right of a claim *B*, situated at a distance, let us say, of 600 ft. from one end of claim *A*, on the same lode, and having end-lines inclined toward claim *A* at an angle of 40°, in a horizontal plane, with the strike of the vein. When the lode is not simple as to strike and branching, the clustering of claims to take up every trifling gap in the ground which had been open for location produces complications that are bewildering. The lawyer insists that he is most competent to protect a mining property by superintending the location of claims to cover the ground, while the geologist is prone to feel the same sort of self-reliance. The fact is that it takes a great deal of experience to do it adequately, and the engineer and his attorney, working in harmony can do better than either one alone. An engineer will invariably find the property to which he is assigned as manager surrounded by a Chinese puzzle of conflicting claims. To assume that former administrations have unraveled the tangle and determined the rights on which the future of the enterprise depends is usually to repose on a couch of delusions. An array of reports, and abstracts of title, may lull the inexperienced, but one who has had a wide range of practice will never be content until he knows the history of every claim in the group, those under his control, and those be-

longing to other people. It is important to have an absolutely accurate map made of the group, showing the claims as described in the notices of locations, and as indicated on the ground by monuments, and as subsequently modified by re-location or by amended location. The geology should be plotted on the general map, and on the claim-map, and the extralateral right and its conflicts with others displayed in contrasting colors so as to be readily followed.

The proof of labor on all claims should be looked up by search of the records, and all work done on them measured or estimated, and checked against the aforesaid sworn statements, bearing in mind that an excess of work and lack of continuity in the recorded affidavits may indicate a gap which could be closed up by the testimony of competent witnesses, and that even in the absence of adequate work, visible on the claim, the testimony of witnesses may substantiate sufficient work done directly on the claim and partly or wholly obliterated, or done exteriorly to the claim but for its benefit. If there ever be any doubt as to ownership or as to validity of title it is safer to assume that possession of the claimant will be confirmed by the courts, since the courts are extremely loath to disturb a man in his possession of real property or to declare forfeiture of title.

A distinction must be drawn between title and patent. A man acquires title by certain acts of his own; by possession and use; by making discovery of valuable mineral and claiming the same in a public manner. The law prescribes the due and proper manner for locating a claim so that the right of the claimant may be indefeasible, but the common law has thrown a mantle of protection around those impeded by ignorance or other untoward circumstances, and a very feeble pretense at compliance with the letter of the statute does affect the land claimed until a court-title has been decreed, and the period for appeal to higher courts has elapsed. Even prolonged abandonment, followed by peaceful possession by others, does not remove the blot so that a title may be considered secure from attack. The safe course is to bring action against the former claimant for quieting title. Abandonment is not easy to prove, and a man's title to a mining claim endures indefinitely, though he perform no annual work upon it, until adverse possession has been made effective, and even then, if he choose to contest possession with the new locator the burden of proof of abandonment lies upon him who would assert adverse rights. Even though a claim may have lain untouched for years, the title is made impregnable by the mere entry of the locator upon it to perform work thereon. It is not a revival of title; it is making the title good against all the world. I have insisted upon these possessory rights because an impression prevails that the rights a man may acquire in real property, and particularly in Government land, are easily forfeitable. The common law idea, however, proceeds from a conception of the man as a part of the soil. The effort to dispossess a prior claimant to real estate commands the serious consideration of the courts. He is hard to shake loose, and the case against him must be so strong as to

leave no shadow of doubt. But for that the claim-jumper would be much more than the thorn he now is in the sides of those who conduct legitimate mining. Nevertheless there should be no negligence in the fulfilment of the requirements of the law to maintain valid tenure. The courts, while loath to reject the most shadowy title, are also inclined to look with superior favor upon the diligent, and diligence has been the determining point in many an important decision. Until a man has made the exhaustive study of the surrounding claims that I have indicated, he is not certain that conflicts may not occur, nor that the expansion of operations, either above or below ground, may not be the signal for kindling the fires of litigation. After such an investigation it will be apparent what need be done in purchase of troublesome or necessary claims, in compromise of rights, or in frank warfare to clear the way of obstacles for the future. Where two interests clash, and compromise fails to remove the impediment to successful operations, the best policy is to fight it out in the courts, and if a fight is inevitable the sooner undertaken the less stamp of enmity and taint of personal bitterness is it likely to leave upon the community.

It would be quite fruitless to single out points and cases in the practice of the mining law for special emphasis. The things I would light upon would not perhaps be the things you would be confronted with; and one matter is as important as another when it happens to be the irritation and threat of trouble at the moment. I will merely insist that an engineer should study the method of locating, and the effect of locating claims, in all their phases. Let me cite a few cases. A re-location is premature if attempted after a prior prospector has made a discovery and begun the acts of location, but before the time allowed him to finish the acts of location has expired. Premature re-locations have been regarded as void, but the case of *Lavagnino v. Uhlig* has thrown doubt upon that contention. Premature re-locations are those in which either a perfected location is not yet forfeitable, or where a prior locator has not yet exhausted his statutory time to perfect his uncompleted location. Another point to note is that in the absence of a survey whereby the exact size of a claim specified in the location notice can be laid out on the ground and accurately monumented, the claimant cannot obtain by patent a greater area than that included within the monuments, regardless of what the location notice may affirm. The maximum statutory size of a mining claim cannot be exceeded in any case, and if the location notice calls for less it becomes the determining guide for the Deputy Mineral Surveyor. Hence if any error be made it were better to deliberately err by setting the monuments so as to stake out more ground than claimed in the document, and then the amount so claimed will be laid out by the surveyor within the staked boundaries, and correctly re-monumented. The excess will be lopped off, and if there be no adverse contiguous or overlapping claimants whose rights might be prejudiced thereby the claimant may elect where the reduction of area may be effected; otherwise the determining feature will be the end-line nearest the

discovery and toward which the course runs for the initial bounding monument of the claim. This end-line determines as to position and length, and the opposite end-line is adjusted as to position by its course.

The location of placer claims involves other principles. The right is not necessarily superficial, but it applies to a deposit which conceivably was once superficial, and is confined within vertical bounding planes on all sides. Where the land has been surveyed the claims are to be taken in rectangular fractional parts of a land section. One individual may take any number of 20-acre claims, but \$100 worth of annual labor has to be performed on each and every claim, hence the law has opened the way to evasion (for that is what actually results in more than 90% of such cases), by providing for so-called association claims. An association of any number of persons not exceeding eight may take up one claim of as many times 20 acres as there are persons in the association, and on one such claim only \$100 worth of work is required per annum. A placer-claim can not carry title to a lode-claim; at least it leaves a loop-hole, and it becomes necessary for the defendant owner of a placer-claim as against an adverse lode-claimant to demonstrate his total ignorance of the existence of a lode on the property at the time when he made his location, and even when he applied for patent thereon. In some cases reasonable doubts arise as to whether a deposit should fall under the classification of a lode or a placer. Such an instance has arisen in regard to certain phosphate deposits in Utah. The claim was made that original lean deposits had become valuable through re-arrangement of the phosphoric acid by circulating waters, producing enriched layers. If such concentration had taken place, there would be no more reason in rejecting application for a lode-claim to such a segregated phosphate deposit than there would be for refusing patent as a lode-claim to a gold vein that represented concentration on the Sandbergian principle by lateral secretion from the enclosing country rock. The question of genesis, then, becomes a matter of great importance, to be determined by the United States Geological Survey as a fact precedent to proper classification of the land. If determined to be a placer—that is, laid down by physical agencies or by precipitation from solution in surface waters, the extralateral right would not apply. But if adjudged a lode, the deposit might be followed on the dip of the stratum for miles, and millions of tons could be indefinitely tied up by a few narrow locations on the apex, and held by the performance of the pittance of \$100 worth of work on each outcrop claim per annum. In this connection it is well to observe that in the eye of the law a lode goes down and not up. If a claim is located, for example, on an outcrop in a valley, and the lode unobliquely turns into the hill and goes upward, such a lode location will not hold it. In the meaning of the statute a lode has a point of departure, a beginning, an apex, and that apex must be found in order to constitute a valid discovery, and thenceforward, save for insignificant rolls in the vein, it must go downward into the earth.

Hence in the case of the phosphate deposits, if held under the lode-law, the right on a syncline would cease in the bottom of the trough.

In all countries but our own the old limitation to vertical bounding planes exists unchallenged. In Mexico is found a body of mining law unexcelled for fairness and protection of the rights of miners and of surface owners with whom he may be forced into association. The principles of our law will not apply in Latin countries. Proceeding from conceptions founded in the civil law, they arrive at conclusions foreign to our sense of legal fitness until that ancient code of wisdom has been made familiar to us by study and by experience of its operation. I refer to this merely to bring into relief the necessity I mentioned in the beginning for studying Roman law. Those of you who contemplate going to Mexico, Central America, Colombia, Peru, Chile, should become accustomed to viewing society and human rights as regulated by the Codex Justinianus; you must be able to actually think in terms of Roman justice, else the new world you plunge into will seem hopelessly out of joint.

The estimated life of an untreated mine-prop is approximately three years, according to W. F. Sherfeese, of the United States Forest Service. With a proper preservative treatment this life may be increased, he says, by approximately ten years, giving a total life for the treated props of 13 years. All of the mine-props, both round and square, in use in the United States, contain approximately 500,000,000 cu. ft. About 40% of this quantity, or 200,000,000 cu. ft., can be advantageously treated. If no preservative methods were used the annual replacement would amount to one-third of 200,000,000, or approximately 67,000,000 cu. ft. of timber. If they were all given a proper preservative treatment the annual replacement would be reduced to one-thirteenth of 200,000,000, or approximately 15,300,000 cu. ft. Hence, by a proper preservative treatment of all mine timbers which can be treated advantageously, an annual saving would result of approximately 51,700,000 cu. ft., equivalent to 310,200,000 ft. board measure, or more than half of the present annual cut.

Annual rentals are usually charged in the oilfields upon leased lands until a well is drilled, after which a royalty on the oil produced is paid. But when an operator in Oklahoma leases from an Indian, the Indian Office forces him to pay \$1.15 an acre a year the first two years; \$1.30 an acre a year the second two years, and \$1.75 an acre the fifth year until he drills; and if he fails to drill in five years, to lose the lease. The effect of these provisions is obvious. It forces operators to drill in spite of over-production. It prematurely tests large areas of land, and brings into development pools which would otherwise lie reserved for years. The demand of some rental for every year that a well is not drilled is an old feature of oil leases which should stand, but the automatic enlargement of this payment from year to year and the limitation of five years are wholly unnecessary and work a great disadvantage to the nation.—R. H. Johnson in *Conservation*.

PRESSURE FILTRATION.

Written for the MINING AND SCIENTIFIC PRESS
By ERNEST J. SWEETLAND.

I have recently made many experiments upon slime filtration to determine the relative rates of filtration at different pressures. The object of these tests was to study the practical side of the problem rather than the theoretical; to obtain information for application in everyday practice rather than to gather data of a highly scientific nature. For present purposes a detailed description of the filter which was used in these experiments is not called for, since like results may be obtained with any pressure-filter wherein filter-leaves or mats of any practical construction are enclosed within a cham-

walls of the leaf by applying suction within the leaf or pressure to its outer surface, filtration will progress, and the cake formed upon the surface of the leaf will be of even permeability throughout, regardless of structure or thickness; for the instant there occurs any point of decreased density, there immediately takes place an increase in the rate of filtration at that point until sufficient slime has been deposited to make the resistance offered equal to that at other points. Modern methods of filtration owe their success largely to this phenomenon, for upon the even permeability of slime-cakes depends the success of displacing dissolved metals. The following experiment offers a splendid example of this automatic distribution of slime to form cakes of uniform density: Three leaves of equal area,

Fig. 1. Resistance to Filtration of Cakes of Different Thicknesses at Varying Pressures.

ber, and the sludge to be filtered is applied to their surface under pressure.

The results herein recorded were obtained in a Sweetland filter-press of 456 sq. ft. of filter-area, with slime which I obtained through the courtesy of the Goldfield Consolidated Mines Co. from the new Consolidated mill, this slime being selected because it was produced by modern crushing and re-grinding methods. During these tests about eight tons of slime was in circulation at the testing plant, and arrangements were made to return the slime to the agitator after each test, so that exactly the same slime could be used in each succeeding test, and thus avoid the possibility of false comparisons by a change in the character of the product under treatment.

Much has been said regarding the even permeability of slime-cakes formed upon submerged filter-leaves, the theory of which applies alike to enclosed leaves in pressure-filters, and to leaves submerged in an open tank, as in vacuum-filters. If a properly constructed leaf be submerged in a solution carrying solid matter in suspension, and a difference in pressure be created between the outer and inner

Fig. 2. Time Required for Washing Cakes at Different Pressure
No. 1, 60-lb. Pressure; No. 2, 50; No. 3, 40; No. 4, 30; No. 5, 20; No. 6, 10.

but of slightly different construction, were placed in the filter, and the filtrate from these was cut out from the general flow and conducted to three separate measuring receptacles, the remaining leaves being left intact to filter as usual. The filter-chamber was filled with sludge, and cake-forming commenced. During the progress of cake-forming three sets of measurements were simultaneously taken from the three leaves, with the following results:

| Time. | No. 1. | No. 2. | No. 3. |
|-------|--------------------------------|--------------------------------|--------------------------------|
| | Filtrate per minute. lb. | Filtrate per minute. lb. | Filtrate per minute. lb. |
| 9:55 | 21.12 | 16.70 | 21.12 |
| 10:00 | 12.10 | 12.02 | 12.52 |
| 10:10 | 9.76 | 9.76 | 9.76 |

Note that in the first measurements all flowed at different rates, and in the second the rates were more nearly equal, while in the third all flowed at exactly the same rate.

My experiments have led me to believe that the point of greatest resistance to the flow of solutions through a slime-cake is at the point of contact between the slime-cake and the filtering medium, and

that to double the thickness of a slime-cake does not double its resistance to the passage of solutions. When canvas is used as the filtering medium the pores are instantly partly clogged when filtration commences, and when the fine pores of the canvas are filled with minute particles of slime a medium is formed of greater resistance than the slime itself. Fig. 1 shows the comparative resistance of cakes of different thicknesses to the passage of solutions at pressures from 0 to 65 lb. per square inch. It will be noticed that the rate of flow is not in inverse proportion to the thickness of the cake. Note, for example, that No. 4 flowed 58% as fast as No. 1, while the cake was $3\frac{1}{2}$ times as thick. In plotting this chart, cakes were formed of the thickness indicated, and clear water was forced through them, first at 5-lb. pressure, then at 10, 15, 20, and so on, a measurement of the rate of flow being recorded after each rise in pressure.

In the preceding experiments no cyanide was used in the solution, the purpose being to study the problem from a physical rather than from a metal-

Fig. 3. Time Required for Displacement at Pressures Varying From 10 to 60 lb. per Square Inch.

lurgical standpoint. The next series of experiments was for the purpose of determining the time required to displace with wash-water the cyanide solution contained in slime-cakes. Cyanide was added to the pulp to bring the solution up to 1 lb. KCy per ton, and fresh wash-water was used to wash the cakes. The results are shown in Fig. 2, where the curves representing the progress of displacement were plotted from titrations of the effluent wash-solution. Effluent solution-samples were taken at intervals of one minute and carefully titrated later. In each case the cakes had been formed for the same length of time (20 minutes) and were about $\frac{7}{8}$ in. thick. All other conditions governing the tests were held as nearly alike as possible, the varying factor being the pressure of displacement. In this series it was assumed that displacement was practically complete when the cyanide strength dropped to 0.1 lb. KCy per ton, or 0.005%. It was found that the cakes were washed with equal thoroughness at all pressures, and the amount of wash-water required was the same in each case, regardless of pressure. The benefit of pressure in filtration is therefore not to increase the efficiency of the water

or barren solution-wash, but to decrease the time required to accomplish it.

The great saving in time effected by washing under reasonably high pressure is apparent. To wash a slime-cake thoroughly requires a certain fixed amount of wash-solution, and the time required to pass this amount of solution through the cake depends entirely upon the pressure at which it is applied. The time required for forming the cakes also depends upon the pressure at which the sludge is applied to the filter-surface; therefore the capacity of a filter leaf in pounds of dry slime per square foot per day depends upon the pressure under which it is operated. The length of time required to wash a cake of this slime $\frac{7}{8}$ in. thick is represented by the curve in Fig. 3, which was plotted from the results shown in Fig. 2. In the test recorded in Fig. 2, it was assumed that when the strength of effluent solution dropped to 0.1 lb. KCy per ton, the cake was sufficiently washed for practical purposes. Another displacement test was made to show the comparative length of time required to completely

Fig. 4. Comparison Between Displacement Curves at 10 and 60-lb. Pressure.

displace the solution in the cake. The curves representing the progress of complete displacement are shown in Fig 4, where a test at 10-lb. pressure and one at 60-lb. pressure are recorded for comparison. The comparison is the more interesting because 10-lb. pressure is about the pressure equivalent of a 20-in. vacuum.

It is interesting to note that the rate of flow of filtrate while washing at 60-lb. pressure was 20 gal. per minute, and at 10-lb. pressure it was 4.16 gal. per minute. At 60 lb. it required 10 minutes for complete displacement, and at 10-lb. pressure it required 48 minutes; therefore the amount of water required was 10 by 20, or 200 gal. in the first case; and 48 by 4.16, or 199.68 gal. in the second case.

The curves show that the last traces of cyanide solution are more slowly displaced than the bulk of solution, which is due to osmotic action between the wash-water and solution. At 10-lb. pressure it required 10 minutes to reduce the effluent wash-solution from 0.1 lb. KCy per ton to zero, which was the total length of time required for complete displacement at 60-lb. pressure. The results of the experiments here recorded, as well as several hun-

dred others I have made, justify me in the conclusion that economy in filtration lies in the use of comparatively small filter-leaves operated under pressure, rather than in large ones with vacuum. The capacity of a filter-leaf is dependent entirely upon the pressure at which it is operated. It seems a useless extravagance to use leaves in such a manner that only one-fourth or one-fifth of their real capacity is developed, and that is what is now being done with vacuum leaf-filters.

Take for instance any sort of vacuum filter-leaf and submerge it in a tank of sludge and operate it as a vacuum-filter. It will take probably three hours to form, wash, and discharge a cake 1 in. thick. Then take the same leaf and put it in an enclosed tank and operate it as a pressure-leaf, using, say, 60-lb. pressure, and exactly the same metallurgical results are obtained, but the time consumed is only about 45 minutes. Furthermore, the use of leaves under pressure will make for higher metallurgical efficiency, because when displacement can be rapidly performed, the washing of slime-cakes will not be slighted for want of time.

Successful use of filter-leaves under pressure is simply a matter of the mechanical design of the chamber containing them. Filter-leaves can be operated under pressure with the same degree of convenience with which they are operated with vacuum, and with a great saving in first cost and in maintenance.

Considering that if it were possible to provide a cover for an ordinary vacuum-filter installation, and operate it under 60 or 70-lb. pressure, its capacity would be multiplied 4 or 5 times, one cannot fail to be impressed by the possibilities.

SODIUM SULPHATE IN SAN LUIS OBISPO COUNTY, CALIFORNIA.

By RALPH ARNOLD and H. R. JOHNSON.

*Deposits of sodium sulphate are found in the lowest portion of the Carriso plain, which extends along and within the northeast boundary of San Luis Obispo county, Cal. The lake known locally as Soda or Salt Lake, in the bed of which this salt occurs, lies wholly within T. 31 S., R. 19 E., and T. 31 S., R. 20 E., and is about 12 to 15 miles west-southwest of McKittrick, Kern county, the nearest railroad station. It receives the drainage from the Carriso plain and the adjoining flanks of the bounding ranges, the total catchment basin including somewhat over 525 sq. mi. The lake has a length of about 5 miles and a maximum width of a little over a mile, and includes an area of nearly 3000 acres. It remains practically dry except in extraordinarily wet seasons. The region in which the deposits occur is of the arid type characteristic of the intermontane valleys of California away from the coast. The Carriso plain has a length of about 40 miles and an average width of 12 or 15 miles and extends parallel to the enclosing mountains—the Caliente range on the southwest and the Temblor range on the northeast. The lowest

point in the plain lies at an elevation of about 1925 ft. above sea-level.

The plain itself is a structural depression which has been faulted down between the Caliente and Temblor ranges and has been sufficiently covered by Pleistocene and possibly earlier debris to mask its real character. Faults, some of them very recent geologically, bound the plain along its northeast and southwest margins. The amount of folding and faulting which has taken place in this region is very great. This intense deformation has, in conjunction with denudation, exposed large areas of soft conglomerate, sandstone, and shale, particularly in the adjacent ranges, to the solvent action of rain, and thus through the agency of running water the soluble salts of these rocks have been transferred, in part, to the lowest portion of the plain. There they have been deposited, through evaporation of the solvent, in a series of saline beds, the chief constituent of which is sodium sulphate. A sample of this salt collected at the surface of the lake, just west of the present evaporation plant, which is in Sec. 19, T. 31 S., R. 20 E., varies from dull to lustrous pure white in color and, though more or less granular, may be easily crushed between the fingers. An analysis of the salt, made by George Steiger in the laboratory of the United States Geological Survey, is as follows:

| | Per cent. |
|--------------------------------------|-----------|
| Insoluble | 0.40 |
| Al ₂ O ₃ | 0.04 |
| MgO | 1.66 |
| CaO | 0.45 |
| Na ₂ O | 40.50 |
| K ₂ O | 0.28 |
| H ₂ O— } | 3.65 |
| H ₂ O+) | |
| CO ₂ | None |
| SO ₃ | 46.12 |
| Cl | 9.27 |
| | 102.37 |
| Less oxygen | 2.09 |
| | 100.28 |

The two analyses below were made by Thomas Price & Son, of San Francisco, the first in October 1904, and the second in November 1905.

| ANALYSIS OF SODIUM SULPHATE CRYSTALS FROM SODA LAKE. | |
|--|-----------|
| | Per cent. |
| Anhydrous sodium sulphate..... | 42.78 |
| Sodium chloride | 0.32 |
| Water | 56.90 |
| | 100.00 |

| ANALYSIS OF DRIED SAMPLE CRUST FROM TOP OF SODA LAKE. | |
|---|-----------|
| | Per cent. |
| Insoluble matter | 0.16 |
| Sodium sulphate | 98.65 |
| Sodium chloride | 0.47 |
| Magnesium sulphate | 0.43 |
| Loss and undetermined..... | 0.29 |
| | 100.00 |

It is stated that tests indicate that the surficial deposit of this salt is from 1 to 6 ft. in depth and is underlaid by a supersaturated solution of the sulphate and water. The deposit offers an almost unlimited supply of mixed salts and its profitable exploitation is dependent almost entirely on transportation facilities, which at present are inadequate.

*Abstract from 'Contributions to Economic Geology, 1908', U. S. Geol. Surv., Bull. 380.

ARE WE PROGRESSING?

Written for the MINING AND SCIENTIFIC PRESS
By S. A. WORCESTER.

While Americans quite generally believe that the majority of modern inventions of most far-reaching importance and of the greatest benefit to mankind have originated in the United States, it is undeniable that the managers of many important and relatively permanent enterprises are slow in the adoption of many of the best known devices for saving labor, fuel, and power, the principal items of expense in mining. When installing new plants, managers often place in use wasteful devices rather than pay a little more for modern apparatus even though the cost would be repaid in a few months. In the lines, for instance, of balanced electric hoisting, and the adoption of the gas-engine, using producer gas and blast-furnace gas, the Germans, Belgians, French, and Swiss have been more progressive than Americans. One remarkably cheap, simple, and satisfactory arrangement, the Koepe hoisting or winding system, which has been used by the Germans for many years, and which is admirably adapted for balanced hoisting at the majority of American coal and many of the metal mines, is, so far as I am informed, unused in the United States. The State of Colorado, with its many millions of annual mine output has but one balanced tail-rope hoisting plant in operation, that of the Liberty Bell mine, at Telluride. Nevertheless, the advantages of tail-rope hoisting are clearly stated in almost every text-book which touches the subject. The complete elimination of dead weight which the balanced tail-rope system effects, saves in many cases much more than 50% of the power cost. It also reduces greatly the size of motor or engine required for hoisting a given load. One of the important advantages of the Koepe sheave hoist over the drum-hoist is that in case of over-winding the rope will slip on the sheave before any great damage is done. Although the Koepe hoist, as used in Europe, is direct-acting, with large and expensive motors or engines, there is no important objection to the use of gears, for hoists of moderate capacity, with much smaller motors. In this form the hoist is about the least expensive plant imaginable. Ropes last much longer with this than with any other form of hoist and friction is probably less than with any other arrangement.

Although the counter-balanced or over-balanced single-compartment hoist has been frequently described in the technical press for a number of years, unbalanced hoists are still commonly being installed for handling considerable tonnages. It is not at all unusual for such a hoist to be wasting more power in hoisting useless dead weight than in useful work hoisting ore; with a correspondingly large coal or power bill. It is a matter for congratulation that the skip is being generally adopted in preference to the cage for hoisting ore. In the Cripple Creek district there was, in 1904, but one skip hoisting plant in operation, whereas there are now ten such hoists in use and a number projected. The total number of hoisting plants in the district is probably less now than at that time.

One of the larger items of expense which should attract the attention of managers is that of hand tramming. Where immense waste dumps of thousands and sometimes millions of tons are made by large numbers of men pushing cars which carry from 1600 to 2000 lb. for long distances, the aggregate expense of tramming, and of maintaining trestles and track, is enormous. To reduce this expense I have designed a side-dump motor-car which is used at two of the mines of the Cripple Creek district. It is operated by the engineer by means of a controller placed conveniently near the hoist. One serious defect in the practice of making dumps with the tram-car is its failure to utilize all available dump-room. One of the mines of this district, having exhausted its dump-room on the hillside below the shaft, has built up an immense dump on the upper hillside, by hauling a self-dumping car up a grade of about 30°. An electric hoist placed at the foot of the dump is used for this purpose. Some mines use side-dumping motor cars operated by a motorman for hauling waste to the dump. These cars are much larger than the hand-trammed car and necessitate heavy and expensive trestles. Many practical methods of eliminating this expense have been described and illustrated in the technical press, in recent years, and a little attention to this detail would result in a large saving of labor and material.

In the line of steam-plant economy, comparatively few operators seem to appreciate to any adequate extent the value of high steam pressures, the expensive use of steam, high temperature of feed-water, careful utilization of waste heat and other well known essentials to steam-plant economy. Not infrequently a mine is found having an extensive steam-plant with a fuel bill of several thousand dollars per month, under the supervision of a well paid master mechanic, yet ignoring some of the commonest and simplest apparatus for saving steam and fuel. In some cases this is the fault of penurious and short-sighted managers. In others of employing poor mechanical talent.

One of the most aggravated and prevalent forms of labor-waste now known consists of the unnecessary use of the shovel in mining and reduction plants. It is used for firing boilers in many cases where mechanical stokers would pay handsomely. It is used for loading mine dumps into tram-cars for re-treatment in mills in cases where a cableway and grab-bucket or a scraper-bucket excavator would save 75% of the total cost of handling the material. The shovel is used in a number of cyanide plants of which I know, for discharging leaching tanks, for leveling charges, and for various operations which should by all means be performed by automatic machines which are now well known. Bins having bottoms too flat and receiving their contents from spouts placed too low, so that they cannot be completely emptied nor can they be filled to capacity without much shoveling, constitute one of the most common forms of labor-wasting devices.

In smelting operations some of the large concerns still employ small armies of unskilled laborers using the shovel, and an equally antiquated device, the wheelbarrow, to transport about one-fourth of the

load that can be handled conveniently with the ordinary mine car. This makes frightful labor costs. Many operators and managers, if I may judge from their practice, carry the general impression that all such apparatus as elevator and conveyor systems, aerial tramways, cableways, grab-buckets, scraper excavators, and other automatic devices of any considerable magnitude, for handling materials, are necessarily cumbersome and expensive, and not to be considered seriously except in connection with complete new plants of large size. The fact is that many such devices are available in the simplest forms and in some cases cost less than the present back-number arrangements. Better results may be easily gained if managers will pay more attention to the possibilities in the use of up-to-date apparatus, and will take advantage of every opportunity to observe the latest practice at the best plants as now in operation in different mining districts. Many operators can improve their knowledge of their business immensely by reading closely the technical press. This constitutes an up-to-date source of information on these subjects which no well informed man can afford to neglect. While it cannot be denied that as a nation we are progressing in the adoption of modern inventions, it must also be admitted that we have still many conservatives who greatly retard the wheels of progress. While each of these obstructionists has an ever ready argument with which to defend his plant against criticism, the argument does not check the waste. In the race of progress it may well be questioned whether we are maintaining a safe lead over all other nations.

KATANGA COPPER BELT.

By F. E. STURT.

*The Katanga copper region lies north of the Congo-Zambesi divide, in the southern portion of the Katanga district of the Belgian Congo, and from 400 to 450 miles north of the Zambesi river. The main portion of the belt is 250 miles long, and varies in width from 30 to 60 miles. It extends 90 miles westward of the Kambove mine, and 160 miles southeast of it. The Star of the Congo mine, which will be the first producing centre of the belt, is some 100 miles southeast of the Kambove. The country lies at an altitude of from 3500 to 5000 ft. above sea-level, with a somewhat rolling contour, and covered with patches of thin forest. The climate is sub-tropical and very healthy. Water is found in abundance, the annual rainfall, which continues over the six months from November to April, ranging from 50 to 60 in. Altogether about 160 distinct copper deposits, many of them small, but many, also, of large extent, have been discovered on the Katanga belt. Upon nearly all these deposits are found ancient superficial workings, indicating generally a more or less organized exploitation upon a scale of considerable magnitude. Only some 15 of the occurrences have been explored up to the present.

The general geological features show a remarkable parallelism with those of the rest of South Africa, so that all the leading systems of the lower end of the

continent as distinguished in the Transvaal and Cape Colony, for instance, together with their principal characteristics, are represented by corresponding strata in the Congo area. In southern Rhodesia, south of the Zambesi and the Rhodesian territory to the north of the river, a similar succession of formations with similar features to those of the more southern British territories have been noted, and these may be correlated with those of Katanga. The rocks of the Transvaal system cover a large portion of the Katanga country, and practically all the mines of the copper belt, as well as those of the Bwana M'Kubwa district, in northwestern Rhodesia, and others on the extension of the copper belt to the southeast occur in the dolomitic series of rocks which are a part of this system. The Ruwe gold and platinum deposit at the western end of the copper belt, as well as the lead-zinc mine of Rhodesia Broken Hill, and the deposits of the Kafue copper belt, in northwestern Rhodesia, are also situated in this group of rocks. The basal rocks of the system form the Wemashi series of conglomerates and pudding-stones. They are more or less conformably overlaid by the Kambove series of dolomites and shaly dolomitic sandstones, which are generally pyritic.

Along the copper belt there exists evidence of a great deal of local disturbance, as shown by folding and contortion, faulting and crushing of the rocks. The cupriferous deposits are nearly always associated with these disturbed beds. The occurrence of a finely comminuted and very much slickensided crushed rock of a talcose or clayey composition is common in connection with many of these disturbances, together with well developed bodies of breccia. A quite general occurrence is noted, also, of a cellular quartzose rock, always developed parallel with the stratification, and evidently derived from the silicious dolomites as is indicated by the rhombohedral cavities contained in it. The cavities are often infiltrated with secondary quartz, and are frequently, also, more or less filled by malachite and asbolane. It is worthy of note that in some of the folded copper-bearing beds, where the different limbs of the fold may be observed close together, one limb is cupriferous and the other barren of copper. In the southeastern extremity of the Katanga field many of the deposits are closely associated with granite rocks. The chief minerals in the superficial portion of the copper deposits are malachite and chrysocolla, although other ores and native copper occur as well. They are usually found as impregnations of the sandstones, or as finely laminated layers in the more shaly rocks, or in the shape of crystallizations filling the cavities in the altered dolomitic rocks. Occasionally they exist as disseminated grains in the sandstones and dolomites, and sometimes are seen as pyritic veins, together with vein quartz. Often, too, there are fine examples of the secondary deposition of cuprite which alters through melaconite to malachite. The axis of the mineralization is always along the strike of the rocks, and the outline of the deposits is generally lenticular, the cupriferous sections merging into the barren unaltered rocks. The ores are always accompanied by gold and silver in small amounts.

*Abstract from *The South African Mining Journal*, October 23, 1909.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

American Merchant Marine.

The Editor:

Sir—In considering the question of national ship subsidy legislation, the fundamental conditions that must necessarily underlie the existence of a mercantile marine, if it is to be maintained in a healthy and normal state, are sometimes forgotten, or disregarded. It is often assumed that, because prior to 1830-40 we possessed, as a nation, the finest commercial shipping list of the day, we ought to have it now, and that it is something of a national disgrace or mortification for the American flag to be so rarely seen in the great ports of the world, and its decline is generally ascribed to the restrictive features of the Morrill tariff and those that have succeeded it. It seems not to be remembered that in the first half century of our national existence our country consisted almost entirely of a narrow belt of settlements along the Atlantic and Gulf coasts, whose merchants and business men were entirely dependent upon the sea for trade. In those days there were no railroads to the interior, and, in fact, no settled interior of any kind. Our surplus production was small and of the crudest kind, as is the case with all new lands. Without rapid transit facilities, settlement extension progressed slowly. Most of the citizens of the Republic looked seaward for their activities. The fisheries grew large and important. Coast and river-borne trade were active, and canal construction was undertaken to aid it. These employments naturally produced a class of laborers looking to the water for a livelihood, and a class of capitalists willing and anxious to invest their money in vessels. Those of the ocean class, finding insufficient employment at home, sought cargoes in all parts of the world. In those days there were fine profits in maritime adventure, and American ships were everywhere in the van.

With the commencement of railroad building from the coast, inland, the whole aspect of affairs was changed. The gaze of the people turned from seaward to landward. A magnificent interior, rich in agricultural possibilities, forests and minerals was found. The working class, believing it could improve its condition by occupying it, and encouraged by favorable laws toward that end, abandoned the sea by the thousands, and emigrated into the Mississippi Valley. Simultaneously capitalists found use for their surplus money in the construction of railroads, fully as profitable, if not more so, than in building and operating ships, and free from some of the perils incident to water traffic. At the same time, also, the profits of ocean commerce began to decline markedly, by reason of the vigorous entrance into the business by other nations, notably England; and European capital, harrassed by the political uncertainties of that part of the world, embarked eagerly in the occupation. Hence American shipping naturally de-

clined, and the immense sea-carrying trade of our country passed into the hands, mainly, of Great Britain, a land with but an insignificant interior area, to whose people the ocean always has been, and always will be, a natural field of adventure.

Since the days of this change Americans have been devoting their energy almost entirely to the opening and development of the magnificent continent they have fallen heir to, and now that the Pacific coast has been reached, and the vast stretches between it and the Atlantic fairly occupied, instead of turning to the sea again, our surplus population and capital is pouring across our northern and southern boundaries into Canada and Mexico. This is almost certain to continue until the Arctic has been reached at one extreme, and the Tropics at the other, and more than likely the latter will be crossed, and American influence and energy continue its march over the land, until the southern ocean and the Antarctic bar further progress. Why not? Why should the normal American take to the water, with its limited scope of activity (fisheries and transportation only) when an unlimited number of other opportunities, equally attractive and far safer commercially, are calling him on the land. With great openings yet available to the working man for homes and occupation in agriculture, forestry, and mining, and to capitalists in transportation, manufacture, mine development, and the improvement and usage of the enormous sources of power on every hand, with a government not only permitting but encouraging individualism, and so producing a generation strongly inclined toward inventiveness and the exploitation of new ideas, with environment fostering peace throughout an entire continent, it will be at least a hundred years before Americans will be inclined to turn their attention again to the oceans of the globe. In the meantime, let those nations, conditioned as are England and Japan, employ, use, and command the sea. It is their natural field; they can have no other. They can use it infinitely better than we. To attempt competition with them in their normal branch of activity would be as futile as for them to use their diminutive land areas in contesting with us the primacy in the production of food stuffs. As deeper thought is given to the subject, it becomes clear that the only reason why protection, as a commercial principle, has been so enormously successful in the United States, is because our country is fitted by nature to produce and manufacture almost everything that the human mind can desire or think of. In other lands, differently conditioned, it yields different results. But there are some activities that even we, if we are entirely wise, will leave to other nations, for the present at least, and among them is sea transportation. It is not our proper vocation at this time.

Among thinking Americans the belief is strong that the recurrent agitation for ship subsidies is fomented mainly by a few who have become during recent years interested financially in an occupation that has proved to be only moderately profitable, because inherently not a natural and normal one; that their aim is, by securing subsidies at the expense of the whole people, to enhance the value of their

investment; that if subsidies were secured, they would not build more ships, or carry the flag into more ocean ports, but instead, would simply close-out their holdings gradually to foreign transportation companies, leaving them to enjoy the benefits of the tax, as long as it was maintained. Will the American people assist in completing such a program? In deciding the question, let the following points be well considered: First, that sea-borne trade at the present time, is an occupation yielding but small profits upon the investment; 3% is a maximum, unless Asiatic labor is employed. Second, that it is not the normal field of activity, at present, for the American. His hands are more than full in other and more necessary and more profitable work. Third, that a nation possessing a great mercantile marine, must, of necessity, possess a great navy to protect it, thus calling for additional insurance on a venture of doubtful advisability.

America has been, for many years, the greatest producer of food-stuffs, and of a number of necessary raw materials, such as cotton, coal, iron, and copper, and is now the second in the matter of manufactures. Year by year we are advancing faster in these respects, as well as in the development and utilization of our power resources, than any other people have in the past, simply because we happen to control the largest body of undeveloped and unexhausted land in the temperate zone. The rest of the world must have our exportable surplus. It would go hungry and shivering and comfortless without it. Let the world come and take it, f. o. b. the seaboard. Let them also build their own navies to protect their own ships. Why should we undertake the delivery of our goods, when the merchants of the globe are crowding to our counters, paying spot cash for everything, and asking only the privilege of carrying their purchases away themselves.

THEO. F. VAN WAGENEN.

Zacatecas, Mexico, November 5.

[We are glad to print the above communication from Mr. Van Wagenen. It brings out a number of points which are worthy of consideration. The facts are largely as he puts them, but the argument was truer 20 years ago than it is today. America is confronted by a keen 'land-hunger', which means not only that the best public land available for agriculture has been taken up, but that agricultural production has not kept pace with the demand for food-stuffs created by the congestion of population in cities and the diversion of laborers to manufacturing and mining. The manufactures of this country are increasing at such a rate that in order to maintain them an outward pressure for markets is becoming increasingly strong. Thus the American is again casting eager eyes over the seas, looking for markets. So far as relations with the greater powers are concerned, there is now some competition with them on their own ground. To be sure, the American pays for this by submitting to higher prices behind his tariff wall, in order to offer his surplus at lower prices abroad. That is another matter. The interest of the mining world in a growing merchant marine lies in the certainty of its producing closer re-

lations with other countries, leading to the development of industries in foreign lands by Americans who will perforce elect to utilize American manufactures, and as we have repeatedly pointed out it will ultimately lead to our control of the metal markets of the world.—EDITOR].

Researches upon Cripple Creek Telluride Ore.

The Editor:

Sir—Kindly give publicity to this letter in reply to Henry B. Haigh's article in your issue of November 20.

John Collins Clancy was never chief chemist of the Portland mill. He worked in our laboratory a few months at day's pay. J. M. Tippet was and is the only chief chemist we ever had and Thos. B. Crowe was his assistant before his promotion. The use of cyanogen iodide in connection with potassium cyanide as a solvent for telluride of gold and the manner of producing it in contact with the ore, was the invention of Mr. Crowe and Mr. Tippet and was never claimed by Mr. Clancy until after he left the service of the Portland company. Our laboratory notes from day to day show this, and Mr. Clancy was not even in the State of Colorado when the experiments were made, as shown by the company's records. The process was abandoned by the Portland company over a year ago on account of the high cost of the chemicals used. The Portland company is not now using in its new mill or any of its old mills any process Mr. Clancy ever used during the short time he was with the Portland company; or any chemical ever suggested by him to us, or any process or chemical that could be construed as relating to any patent or suggestion of his, even in the most remote manner.

THE PORTLAND GOLD MINING CO.,

By FRANK G. PECK, President.

Colorado Springs, Colorado, December 2.

Gold in copper bullion may be accurately determined as follows: Dissolving the Cu in conc. H_2SO_4 affords some Cu_2S in the residue. If, however, some $CuSO_4$ is used with the acid but little sulphide is formed. Hence treat one assay ton of the borings with a mixture of 80 c.c. conc. H_2SO_4 and 25 c.c. of a 16% $CuSO_4$ solution. When action stops, cool, stir in 400 c.c. water, bring just to a boil, and filter. Dry and ignite the filter, and then scorify with 35 gm. Pb and 1 gm. SiO_2 . Cupel and part. If Ag is to be determined, oxidize the filtrate with $KMnO_4$, add 1 c.c. of saturated solution of NaCl, then 10 c.c. of 10% $Pb(C_2H_3O_2)_2$, let stand over night, filter, and add the precipitate to that containing the Au, before scorifying.

Stibine, SbH_3 , according to nearly all of the textbooks, when passed into dilute $AgNO_3$ affords Ag_3Sb as a precipitate. Reckleben believes this to be true, but that almost immediately a reaction occurs between the Ag_3Sb and excess of $AgNO_3$ which affords Ag and H_3SbO_3 , the latter in quite insoluble form, so that but little Sb, though always a perceptible amount, re-enters into solution. The reaction, therefore, is essentially parallel to that with AsH_3 .

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Grams per metric ton may be converted into Troy ounces per ton of 2000 lb., by multiplying the number of grams by 0.02922.

Reheating compressed air under favorable conditions will increase the efficiency about 20%. This is done at a comparatively insignificant outlay for fuel.

Colombia annually exports to the United States over \$500,000 worth of gold, much of it in the form of gold-dust. The platinum exports are small, and are exceeded by emeralds, the shipments of which have a value of about \$40,000 per annum. Other minerals exported amount, in value, to about \$60,000. Small exports of asphaltum are also made, worth about \$10,000 a year.

Extraction of gold will usually vary with the original assay value of the ore when treating material of similar character from the same mine. This is conditioned, apparently, upon the fineness of crushing the ore, since changing the mesh of the battery screens, or making other adjustments to alter the grade of comminution, will shift the point below which no further extraction can be effected.

Coagulation of slime in gold ore by means of lime has sometimes been observed to reduce the percentage of extraction, and also to reduce the recovery of concentrate. Coagulation by acidulation is said not to produce such a result. The lessening of extraction with certain ores by coagulation is due to locking up of suspended particles of sulphides or of extremely fine gold in the flocculent masses of slime.

Slags used in smelting lead ores are usually monosilicates, the bi-silicates not being suitable as they carry away too much lead as a silicate. They are also more viscous, and cause irregularities in the working of the furnace. The mono-silicate, however, requires more base for fluxing the silica and is, therefore, not always economical, and other slags are aimed at, having oxygen ratios of 2 to 3, 4 to 5, and so forth. The type formula of the mono-silicate is $2RO \cdot SiO_2$.

Wolframite and hübnerite are closely similar minerals, the former containing iron, while the latter is merely a tungstate of manganese. The two are usually associated. The occurrence of hübnerite which was first described was at the Erie and Enterprise veins in the Mammoth district, Nevada, in argillite, that is, slate of a dense fine texture, where it also was associated with scheelite (tungstate of lime), fluor spar, and apatite. These minerals, however, generally occur in granites, gneisses, and similar rocks, and in almost all tin deposits.

Foundations for structures on loose gravel may often be made sufficiently strong by driving pipes, 2 to 3 in. diam., the pipes being perforated. After driving to the required distance the pipe should be

cleaned out, which can be done with an ordinary sand-pump, such as used by well-drillers, and thin grout, then forced in under head sufficient to cause it to penetrate the surrounding gravel. The pressure required will vary from 60 to 120 lb. per sq. in., the higher pressure being required when considerable sand and argillaceous matter are present.

Flowage of rocks without fusion occurs under simple pressure by a process of granulation, or changing of position of the grains of which it is composed. This may take place without fracture, that is, without the opening of cracks, the whole mass moving like a plastic body. According to C. R. Van Hise the maximum possible depth of the zone of fracture for the strongest rocks under quiescent conditions is not greater than 10,000 to 12,000 metres, and for the majority of rocks the zone of flowage is reached at much shallower depths. The openings of the zone of flowage are chiefly subcapillary.

Superheated steam losses are greater at high velocity of flow through the delivery pipe than at low velocity. The temperature-fall from the centre to the circumference of the pipe is less, and therefore the temperature of the pipe is higher, the temperature-difference between it and the air greater and so the loss is greater; while at low velocity these effects are reversed. The steam has longer time in which to cool, but the fall in temperature across the cross-section of the steam-column is greater, and hence the temperature of the pipe, the temperature-difference between the steam and the air, are less, effecting a lower absolute loss.

Hydrogen peroxide, or hydrogen dioxide (H_2O_2), useful as a sub-cutaneous injection in cases of cyanide poisoning, is formed when barium dioxide is treated with hydro-chloric acid or with dilute sulphuric acid, according to the following reactions:

In the latter case the barium sulphate formed being insoluble the solution may be clarified by filtration. Distillation of the liquid in a vacuum, repeated several times, results in concentration of the peroxide, which when pure, boils at 84 to 85°C. at normal pressures. It is an unstable compound, and deteriorates on keeping.

Cinder concrete is untrustworthy as regards strength, but sometimes is used in a 1-2-4 mixture with a compressive fibre-stress of 200 lb. per square inch, thus classing it with burnt clay, but it is not good practice, and so cannot be recommended. The cinders should be carefully selected and freed from ashes. In the majority of cities cinder concrete is not allowed to be used in spans exceeding 4 to 6 ft. When greater spans are permitted they are never more than 10 ft., and must be designed after testing a sample slab or beam to destruction, using the data thus obtained with a factor of safety of 10. The ultimate strength of good, well made cinder-concrete is about 900 lb. per square inch in compression at the end of 30 days with a 1-2-4 mixture.

Special Correspondence.

MEXICO.

Pachuca.—New Locations.—Santa Gertrudis. — Santa Barbara, Chihuahua.—Batopilas Re-Organization. — Casas Grandes Smelter. —Palmilla.—Douglas Copper, Sonora.

The Argentina y Anexas mines, a group in the Chico district to the north of Pachuca, have been sold to Howard T. Oliver. It is stated that heavy investments will be made, and the mines will be developed and worked on modern lines. These properties are well known and have been large producers, but have not been worked to any extent for some time past owing to lack of capital. The fraudulent use of a name for the promotion of a mining company, that is similar in the name to some famous and well known mine, is an old trick. A hole in the ground in the Taxco camp was recently passed off as a mine, and a company floated in the United States under the title of the Dos Estrellas Mines & Development Co. Fortunately the scheme has been

Street Scene in Pachuca.

squashed by the United States postal authorities as being an improper use of the mails.

A company is to be promoted in the United States to develop a group of promising prospects and mines in the Zacualpán district. The most important of these are the Genoveva, the Santa Ines, and the Concepción. Alfredo Chabaund, the general manager of the Cuchara mines at Zacualpán, is the moving spirit in the enterprise. Referring to the work in progress at the Seguranza Mining Co.'s properties at Zacualpán, everything is now about ready to start the mill. The mine has been unwatered, ore is being taken out, and connections have been opened between the Zaragoza and Coronas levels. Some good milling ore has also been developed in the workings of the Ampliación de Olivado, a claim that was recently purchased. The electric sinking pumps and air-drills, lately acquired, are being transported to the mine. The 100-ton mill that has been erected, is now completed, and the only delay is due to the time required for the completion of the power-line between Sultepec and Zacualpán. It is expected that the whole plant will be in running order by the beginning of the year.

The cyanide plant of the Santa Gertrudis y Guadalupe company at Pachuca is nearing completion and it is expected that at least part of the plant will be ready by the middle of January. Messrs. White and Newcomb deserve credit for the speedy way in which they have handled this job. The unwatering of the Angustias, Dolores y Anexas

group is steadily progressing. At level 10 good ore-shoots have been found from 40 to 95 metres long. About 200 tons of ore per week is being taken out, averaging about 400 grams silver and 11 gm. gold per ton. It is expected that the cyanide plant will be put into commission about the end of December. The richer ore is being shipped to the Aguascalientes smelter. A group of some 50 capitalists and other influential men are paying a visit to Mexico under the guidance of Mr. Stilwell. Among the members of the party is John F. Wallace, former chief engineer of the Panama Canal. The gross earnings of the National Railways for the third week of November were \$82,484 more than the corresponding week of last year, this being an increase of 7.3%. At the Sonora & Ures mine, which is on an extension of the La Blanca vein system, a small, rich ore-shoot was struck, and it is thought that this is an extension of the new rich vein found in the La Blanca recently. The Sonora & Ures mine is one of a number of the new properties that have been taken up and developed on extensions of the Santa Gertrudis and La Blanca vein system. To a Nevada 'boomer' it would be absolutely incredible that all of these extensions had not been taken up and worked long ago, in view of the fact that the vein system is known to extend beyond the limits of the properties of the Santa Gertrudis, La Blanca, and Barron, both on the strike and on the dip. Nearly all of the ground has now been denounced, but it has not yet been explored. Diamond-drilling would be an easy means of testing the value of the extensions of these veins. The above condition is all the more remarkable in view of the success of so many of the established mines at Pachuca. For example, the San Rafael y Anexas paid a monthly dividend of \$86 per share. The Santa Gertrudis is paying regularly \$1 per share per month, or approximately 12% per annum on the par value of the shares, and this, notwithstanding the fact that the company is erecting its new mill and cyanide plant out of the profits without curtailing the 12% dividend. Other notable monthly dividends are Maravillas \$4; San Francisco Hacienda \$2, and Guadalupe Fresnillo \$5 per share.

R. A. Lyman, assistant general manager of the Real del Monte company at Pachuca has resigned.

Three large properties in the Santa Barbara district of Chihuahua are being operated by the El Rayo Mining & Development Co., treating on an average 4500 tons per month by the cyanide process, with good results. A large 250-ton mill is to be erected about seven miles from Parral; between the towns of Minas Nuevas and Parral. A spur is being built to the mill-site from the new Parral & Durango railroad; the manager for the company is James J. Long. The Batopilas Mining Co. controls about 1600 acres of titled mining property in the Batopilas district of Chihuahua. Besides this, the company obtained a Federal concession covering the mineral rights to about 61 square miles of territory in the same district. The Batopilas Mining Co. was formerly controlled by Alexander R. Shepard. A new company has now been formed in England with a capital of £300,000 under the title of the Batopilas Mining, Smelting & Refining Co., Ltd. According to a report just issued by L. H. Stephens, president of the old company, a contract has been entered into with the new one by which the latter will lease the existing mines, mills, and haciendas. This will include the Todos Santos, Cinco de Mayo, Ballinas, and San Miguel properties. Under terms of the lease the new company will increase the output and will also make improvements in the 100-ton mill, and will erect a large cyanide plant. It appeared that the old company will receive and control 250,000 out of the 300,000 shares of the new organization, and that the latter will pay off the bonded indebtedness of the old concern, including principal and interest. The term of the contract is for 25 years. Gilmore Goodland, an English mining engineer, has been making examinations and reports on the properties. Alexander R. Shepard, Jr., will remain as general manager.

The Cole-Ryan interests are extending the plan of operations at the Sierra Consolidated Mines Co.'s properties at Ocampo, Chihuahua.

The El Rayo Mines Co., owning mines near Santa Bar-

bara, Chihuahua, has been making net returns of \$5000 to \$20,000 per month, and this month a quarterly dividend will be declared, payable in January. The capitalization of the company is \$75,000.

A rich ore-shoot has been struck in the Dos Cabezas mine near Casas Grandes, Chihuahua, and extensive development work is in progress. Additions are also being made to the working force; the new main shaft has been completed; and the additional machinery which was ordered some time ago, is now being erected. The company is making plans for the construction of a smelter near the mines. J. L. Hirt is manager. It is rumored that the Candelaria Mining Co. has sold the well known San Pedro silver mines to F. S. Pearson. These are in the San Pedro district in the northern part of Chihuahua, on the line of the Rio Grande, Sierra Madre & Pacific railroad. The construction of a railroad from Durango to the Murphy tract seems to be now a settled fact. It will be 100 kilometres long and the estimates call for an expenditure of \$2,000,000. It is also stated that three branches will be built, and that a large creosoting plant will be installed in conjunction with the enterprise. Besides opening up a valuable timber and agricultural tract, the road will facilitate the development of a number of mines.

The contract for the building of the waterworks and drainage systems of Chihuahua has been awarded to the Cia. Bancaria de Obras y Bienes Raices of Mexico City. The Palmilla Milling Co. has ordered machinery for a 1000-ton mill from the Allis-Chalmers Co., and has also ordered machinery for a steam-electric central station power-plant from the Minneapolis Steel & Machinery Co. The steam engines will be cross-compound condensing Corliss type, direct connected to the electric generators.

The news comes from Sonora that two large companies have merged their interests, the Douglas Copper Co. and the Mexican Exploration & Mining Co. The Douglas Copper Co. owns the El Cobre mines and the smelter at Fundicion which is on the Southern Pacific of Mexico railroad. The smelter is designed for an ultimate capacity of 1000 tons, and has one 350-ton unit completed. The Exploration company owns a valuable mineral concession covering 1,500,000 acres, west of the Yaqui river, and north of Cumuripa. More than 50 locations have been made on this tract, and the developments have shown sufficient fluxing ore for the output of the El Cobre mines. The new company which will control the merger has a capital of \$6,000,000 common stock, and \$2,000,000 of 7% preferred stock; \$1,500,000 of common and \$600,000 of preferred stock have been reserved in the treasury.

CHICAGO.

Cherry Disaster.—Work of the Helmet Men.—Mine Rescue Stations.—University School of Mines.—Fire Protection.—Indemnity Insurance.

The Cherry disaster continues to be the main topic of conversation. It will be recalled that early in the year a Mine Rescue Station was established at the State University by the United States and State Geological Surveys, jointly, and R. Y. Williams placed in charge with J. R. Webb as assistant. Since its establishment the State Mine Inspectors have heartily co-operated, becoming themselves thoroughly familiar with the apparatus and frequently calling on the men in charge for assistance in fighting mine fires. The results accomplished at Cherry by the Inspectors and the men from the Station afford an appropriate occasion for reviewing the work so far done. The main object in establishing the Station was to demonstrate the use of the new mine rescue tactics, to train men in the use of the oxygen breathing apparatus, and to study the mining conditions in the Eastern Interior coal field, with a view to lessening the hazards of coal mining. When the engineers from Urbana, with their 1300 lb. of baggage arrived at Cherry, the shafts were sealed and rescue work at a standstill. This sealing of the shafts was caused by both shafts being on fire, and it was, naturally, unwise to allow any ventilation to pass through the mine under these conditions. Considerable quantities of water had been poured down the air-shaft in order to try to put out the fire, but there was no assurance

that this had been successful until the oxygen helmets were used to enable the men to make a thorough inspection of the air-shaft and the entries immediately contiguous on the upper level. When this inspection had showed that the fire was out in the immediate vicinity of the air-shaft, it was considered reasonably safe to descend the hoisting shafts with a view to establishing circulation sufficient to cut the smoke, and fight the fire at the foot of the hoisting shaft and between that and the air-shaft. Inspections of the hoisting shaft were made with the aid of helmets before this air was turned in, but the smoke was so thick that the fire could not be found. After the starting of the fan, the flames were easily discovered and the hose taken in by the helmet-men in an endeavor to extinguish the blaze, but at this critical juncture, it was evident that there was no head of water obtainable, and, consequently, the shafts had to be re-sealed until a dependable supply of water could be had. As soon as this was obtained and the firemen from Chicago were on the ground to render their ready and valuable assistance, the shafts were again opened and the fire controlled sufficiently to allow the progress of the rescue work. One week after the fire had started, while a corps of rescuers was digging through a wall 600 ft. from the shaft on the west side, voices were heard and eight entombed miners were found to have walked and crawled 3000 ft. from the head of an entry where they had walled themselves off a week previous. These men told of 12 of their companions who were on the inside of this barricading wall and who were too weak to join the eight who had found their way to the shaft. Owing to the presence of black damp, it was impossible for the rescuers to enter the region through which these eight men traveled. Consequently, ventilation was established in these entries and carried to within 100 ft. of the barricade wall. At this point the helmets again showed their ability to handle situations which heretofore would have been impossible. With their aid volunteers rushed through the black damp to the place where the 12 men were confined, and rendering them support, brought them out to the point where there was ventilation, and restored them with pure oxygen before sending them to the surface. Some of the men, obtained in this way with the aid of helmets, were unconscious, and the temperature of their body was low, but they were all revived by means of the oxygen treatment. It is thus evident that with the aid of the oxygen helmets the Cherry mine was opened up a number of days earlier than it would have been otherwise possible, and also that when the live men were discovered 12 were immediately rescued with the helmets, whereas without the helmets there would have been necessary delays and the possible loss of the men.

Several other cases where the helmets have been used to advantage may be cited. At the time of the explosion of Dering 18, West Frankfort, Illinois, in February, 1909, the helmets were used to assist in sealing the air-conduit leading between the air-shaft and the fan; and at the same mine on June 7, an inspection of the air-shaft from top to bottom was made by men wearing the oxygen helmets. During the summer at the Hart-Williams mine, Benton, Illinois, a fire originating from a blast of black powder was sealed up temporarily. Five days later the oxygen helmets were used to inspect the seat of the fire, to erect brattices, and to remove the large amount of explosive gas that had collected. The fall caused by the fire was then loaded out. At Moweaqua, Illinois, last September, a fire that originated in the timbers at the main shaft-bottom was successfully handled with the aid of the Urbana apparatus. This was a very serious fire when discovered, and the helmets showed clearly that the only alternative would have been to have sealed the shafts indefinitely. During December at the Majestic mine, near DuQuoin, Illinois, a fire that had raged ten weeks previous, was extinguished with the aid of the new mine rescue tactics. Owing to circumstances at the time of the fire, fully 40 acres had been sealed off, and had filled with marsh gas during the intervening period. The helmets were used to allow inspection of the immediate fire region, and to assist in the removal of this enormous quantity of gas, after which the heavy fall that had been caused by the fire, was loaded out. During this work, the coal

again began to glow, but the fire was controlled with the aid of fire extinguishers. It is evident that the Station is accomplishing much good and it has already won the enthusiastic support of miners, operators, and inspectors. It is hoped that district stations will be established and equipped throughout the Middle West by the co-operation of the operators, so that the apparatus and corps at Urbana may devote more time to general studies and the training of men.

In part as a result of the establishment of this Station, a mining school has been organized at the university in response to the request of the operators, miners, and coal users. H. H. Stoek, already well known in Illinois through his connection with *Mines & Minerals*, has been called to its head, and is now organizing the work. It is planned to develop courses especially for coal miners and the department announces that it stands ready at any time, by lectures or other means, to co-operate with and assist any organization in the State that aims to help those who are preparing to take the examination for Mine Manager, Examiner, or for Hoisting Engineer, or which aim to assist the ordinary miner to better understand his daily work.

The mining and metallurgical industry of Illinois represents an output valued at approximately \$150,000,000. The general public is, however, so accustomed to consider Illinois as agricultural, that it does not realize that the State ranks third in the amount of mineral and metallurgical output, being surpassed in this respect only by Pennsylvania and Ohio. For many years Illinois has occupied second place among the coal-producing States, and the rapid development of the iron industry about Chicago and around the southern end of Lake Michigan has already placed it well up among the iron and steel producing States. As a producer of petroleum, of clay, and of sand products, also, Illinois stands well toward the front. It is, therefore, eminently fitting that the mining industry should be represented in the State University and the Department will evidently find abundant opportunity for good work.

A special session of the General Assembly has been called by the Governor, C. S. Deneen. Among the matters recommended for legislation are several touching mining. Better protection from fire and the provision of adequate fire-fighting apparatus is recommended and doubtless will be required. In the face of the loss at Cherry its need can not be denied. The Mine Casualty Committee of the Operators' Association has already had the matter up and a number of companies have taken independent action. There will always, however, remain a few that can be reached only by legislation and in any event a law setting minimum requirements is desirable. Another matter recommended by the Governor is a commission to study industrial indemnity insurance. There is a strong movement toward the creation of a fund by means of a tax on each ton of coal mined, to be used to relieve dependents in cases of accidents. The excessive cost and waste of the present method whereby the bulk of the money goes to contesting claims, has been abundantly shown and such a tax would be in line with the modern doctrine that each industry should provide for its own losses. If the matter can be adjusted so as not to upset present competitive conditions among the coal fields, it will not be opposed, but it is not easy to see how this can be brought about. It is rumored that the United Mine Workers of America will include in their demands next spring, one for a flat increase of 10% in wages, the money to be paid into such a fund. This plan has many advantages since the agreement would, if so effected, be inter-state. It has the defect that non-union districts would be given further advantages in the markets and that in any event the operators would not be relieved from legal obligation, damages, nor would they be protected from suits. This, of course, would be unjust. Evidently the commission Mr. Deneen has asked for is needed. The productive capacity of the mines greatly exceeds the annual demand. There is ruinous competition and small operators are being driven out of business and combination to regulate production is out of the question because of the anti-trust laws. These economic conditions are largely responsible for the present waste in mining and in part for the large loss of life.

WASHINGTON, D. C.

New Bureau of Mines Bills.—Conference for Uniform State Laws.—Phosphate Land Legislation.—Land Withdrawals in Montana.

The second session of the Sixty-first Congress, which convened Monday, December 6, was not a day old before a number of bills calling for the establishment of a Bureau of Mines in the Interior Department had been dropped into the legislative hopper. It will be remembered that the last House of Representatives passed such a bill by an almost overwhelming vote, but the bill did not get an opportunity in the Senate, being called up in the closing hours and talked to death by Mr. Teller, of Colorado. At the extra session of Congress, bills were introduced by Charles Dick, senior Senator from Ohio, Joseph M. Dixon, Senator from Montana, William F. Englebright, of Nevada City, California, representative, William B. Wilson, of Blossburg, Pennsylvania, representative, Harry M. Coudrey, of St. Louis, Missouri, representative, and Albert Douglas, of Chillicothe, Ohio, representative. All of these bills are still alive, and will remain so until one bill is passed or the Sixty-first Congress ends. This week three more bills have been in-

Western Phosphate Lands.

troduced in the House of Representatives, calling for a Bureau of Mines, one by Martin D. Foster, of Olney, Illinois, one by Richard W. Austin, of Knoxville, Tennessee, and one by Charles N. Pray, of Fort Benton, Montana. These bills follow in a general manner the previous ones, with the exception of that offered by Mr. Pray, who would give the Commissioner of Mines a salary of \$7500 per year. All of the bills provide for the transfer from the United States Geological Survey of the work now being done by the Technologic Branch. That both Houses are determined to get early action on the bureau of mines proposition is seen in the fact that both committees on mines and mining have already held meetings and discussed the various bills. The House Committee, with George F. Huff, Greensburg, Pennsylvania, as chairman, has already indorsed the Douglas bill with certain minor amendments. This bill follows closely the bill passed by the last House, with the Senate amendments attached. It is impossible to learn just what changes have been agreed to until the bill is reported out of the committee.

On January 17, 18, and 19, an important national conference will be held in Washington between employers and employees and men high in the councils of the nation on

the subject of greater uniformity in State laws. President Taft has promised to make the principal address. One feature of the conference, and the one most interesting to the mining interests, will be a discussion of the need of uniform mining laws in the various States, especially in the coal-mining States, where different laws with different requirements, it is claimed, sometimes work hardships upon the coal operators. For instance the laws of certain States demand costly safeguards for the miners that are not required in other States, these adding to the cost of the coal in these States and giving the operators of the other States undue advantages. The conference in seeking this uniformity will endeavor to raise the standards of the States whose safeguard requirements are not adequate, and in this manner equalize the competitive conditions. John Hays Hammond, John Mitchell, and Joseph A. Holmes of the Geological Survey, are expected to aid in this movement.

Gilbert M. Hitchcock, of Omaha, Nebraska, representative, has introduced a resolution in the House calling for the appointment of a committee of seven to make a complete investigation of the conduct of the General Land Office during recent years with relation to coal lands and other public domain in the Territory of Alaska. Reed Smoot, Senator from Utah, has the honor of introducing the first bill at this session relating to mining. His bill provides for the utilization of the phosphate deposits belonging to the United States, and calls upon the Secretary of the Interior to restore to entry such of these lands as may be without prejudice to the United States, after they have been classified by the Geological Survey. The bill provides for a commission of three members which shall proceed to clear the title of these phosphate lands of all entries, claims, and locations invalid because of non-discovery of mineral, failure to perform the annual labor required by law, or because of failure to perform any of the material acts required by law as a pre-requisite to entry. The bill further provides that the Secretary of the Interior be empowered to issue leases to work the phosphate deposits on such terms as he may deem best.

John B. King, of Texarkana, Texas, is before the General Land Office with a unique proposition. He is evidently a shrewd citizen, and if he is successful in his contention, he will be richer by a sum estimated at \$5,000,000. Mr. King lives near Ferry lake, a body of shallow water, 4400 acres in extent, in Louisiana and Texas, in the famous Caddo oilfield. Several years ago Mr. King, according to his own statement, while prospecting over the general oilfield in the district where the lake is situated, discovered that while the Standard Oil Co. had located its wells on all sides of the property, no attempt had been made to locate on the lake. He then went to work, he says, and made a close examination of the records bearing on the question of title to the land on which the lake lies. This was formerly government land, before the backwater from the Red river overflowed and left the lake. He ascertained, so he claims, that the lake was never turned over by the general Government to the State of Louisiana, and he lost no time in making an entry on the 4400 acres in question. One year ago Mr. King made the entry under the placer-mining laws, and he is now before Commissioner Dennett endeavoring to perfect his title before beginning operations. He says that the lake is but two or three feet deep, and that it will be an easy matter to locate oil wells in all parts of the 4400 acres. The State of Louisiana, which it was thought would claim title to the lake, has not put in a defense. Mr. King is represented by former Representative John J. Lentz, of Columbus, Ohio.

Announcement has been made by the Interior Department that about 1,000,000 acres of land in northern Montana, reserved by the Government for the purpose of allotting it to Rocky Boy's band of Chippewa Indians has been restored to settlement and entry, and that the Indians are to be given allotments on a small portion of the Blackfoot reservation. For use in connection with the Fayette-Boise reclamation project, Idaho, Richard A. Ballinger, of the Interior Department, has withdrawn from all forms of disposition about 49,000 acres of land needed for the enlargement of existing reservoir sites.

GOLDFIELD, NEVADA.

Production.—Consolidated Mill.—Clermont.—Florence—Goldfield.

Production is maintained in the Goldfield district averaging well above \$200,000 weekly, with the Consolidated and Florence leading, and small shipments from a number of leases being sent to the local samplers. Official estimates place the output of the Consolidated for the month of November at 19,180 tons, with a gross recovery of \$635,000, and estimated net profits of \$480,000. Final returns have never, thus far, failed to surpass the estimates given out by the management. At the Consolidated 100-stamp mill on Columbia mountain, additional equipment is being rapidly installed, which will increase the capacity of the plant to 900 tons daily. While the stated capacity of the mill as first constructed was 600 tons daily, it has for several months been treating 650 tons. The new equipment includes six 6-ft. Chilean mills, 26 Deister concentrating tables, four 8-ft. Callow classifying cones, two additional agitators, an electric pump, compressor, and two elevators for hoisting the oversize back from the tube-mills to the classifiers. No additional structural work has been necessary, there being ample room in the present mill structure for the new equipment, and the refinery is capable of handling the product of the entire plant.

New stopes of large dimensions are now being opened in the Clermont workings on the 750 and 900-ft. levels, as well as on intermediate levels between the 600 and 900. The west cross-cut, at the 1000-ft. level, toward the Mohawk vein, is out over 400 ft. and is expected to penetrate the vein opened above early in January. At this depth the formation is identical with that at 900 ft., where large bodies of ore are exposed for a distance of 350 ft., the ore being of excellent milling grade, and averaging 20 ft. wide. The best showing is still at the 750-ft. level, where the sill-floors are 25 ft. wide, and for the entire width the ore averages \$500 per ton. Beyond this width are additional bodies of good milling ore. In one raise from this to the 600-ft. level the ore broken averaged nearly \$3000 per ton throughout. In this orebody are many seams carrying free gold and telluride in large quantity. Good ore has been followed in driving to the south on a cross-vein for 70 ft. from the main vein, and a stope 8 ft. wide is being opened on this lead at an intermediate level. The 750-ft. level has now been driven 900 ft. from the Clermont shaft to a point from which a raise will tap the deposit containing some of the richest ore found in the Mohawk. Other raises will connect with the orebodies of excellent character opened in drifts from the 50-ft. winze below the great stopes at the southeast of the Mohawk. The 600-ft. northwest lateral from the Clermont has penetrated the Red Top vein at the point where it turns to the west, and below the stopes at the 260-ft. level, but no ore of high value has been found at this depth in the vein. A large tonnage of excellent milling ore is being opened in cross-cuts driven into the foot-wall of the main Mohawk ore-shoot where 20 ft. of \$30 ore has been opened. South on the Mohawk the work has had equally good results in driving under the old lease-stopos, and a good vein of high-grade ore has been opened nearly to the boundary of the Combination Fraction. An old cross-cut at the third level to the west is being cleaned out and will be extended into the Combination, cutting through the country rock a short distance north of the Hampton stope. Throughout these mines development is being pushed as never before in order to prepare for the increased demands of the mill. The company now employs about 750 men and its payroll for November approximated \$80,000.

The past three months have witnessed a large increase in the ore reserves of the Florence-Goldfield mine, and the perfection of the mill to a point rendering it one of the most economical and efficient of its capacity in the State. With a new 200-ton gyratory crusher and other improvements, the plant is now treating 160 tons of ore per day and making a highly satisfactory saving of the gold content of the ore. The new mill-superintendent has dispensed with the use of blankets, which were employed on a portion of the plates, and has resumed direct amalgamation with the result that in some of the product 60% of the gold is being saved as

the amalgam and 40% of that formerly contained in the concentrate, making an appreciable saving in transportation expense. Troughs, launders, and other woodwork, with which the ore has come in contact in various stages of treatment, have been subjected to a thorough cleaning, and a considerable amount of gold recovered that had adhered to them. Shipments of concentrate are made regularly to the smelters, and the mine is now in condition to make good profits. It is stated that the ore reserves are ample in the territory adjacent to the company shaft and above the 400-ft. level to supply the mill to its full capacity for more than a year without further development. The mill-heads have lately approached an average of \$30 per ton.

The main workings of the C. O. D. Consolidated Co. on the Gold Bar claim have been acquired under lease for a term of five years by local and Eastern men, and active development will begin shortly to open the mine at depth, and the lessees will soon begin the construction of a 50-ton mill. The lease embraces 20 acres, with veins from which a considerable tonnage of high-grade ore has been produced. It is estimated that there is already available on the dumps, and broken in the workings, 1000 tons of \$25 ore that is free milling. The mine is equipped with an excellent hoist-

Florence Mine, Goldfield, Nevada.

ing plant and a 3-drill compressor, which will be supplemented by additional power. It will require a month to clean up the workings and install a higher head-frame, after which the 325-ft. shaft will be sunk to the 500-ft. level, and the veins will be explored at that depth. The enterprise is headed by B. E. Thomas, who has exposed shipping ore in his lease on Columbia mountain, and it is designed to have the mill on the Gold Bar treat the product from this lease. L. K. Koontz, manager of the C. O. D. Consolidated, has announced that he will develop the Victor claim and veins from which a good yield of high-grade has been made in that ground, from the 600-ft. shaft of the Gold Ore Mines Co. on the north line of the Gold Bar claim.

Development on the Nancy Donaldson, in the eastern part of the district, has exposed some pay-ore at the 125-ft. level, and driving is in progress on the vein from which assays were secured at the surface running into thousands of dollars. The shaft has been heavily timbered, adequate mining machinery installed, and sinking will be continued. The vein has a foot-wall of porphyry and quartz, characteristic of the productive veins of the district. Lessees on the Goldfield Daisy are producing a small tonnage of good ore. A new hoisting plant has been installed on the Millard-Jones lease on the Daisy, where shoots of high-grade ore have been opened at two points. The Belmont continues to take out shipping ore, and the workings of the company are being extended at depth. Atlanta lessees are working energetically and opening new territory near the extension of the Clermont vein. Shipping ore is being broken in the original St. Ives workings by William MacKay and associates, and have also leased the main shaft of the Merger Mines Co. Medium-grade ore is being shipped from the old Graham shaft on the Daisy. The demand from the smelters for silicious ores has caused a reduction in charges made by local ore-purchasing and sampling companies to \$9 per ton on some classes of ore, and this will afford an outlet for a large tonnage of the Goldfield product.

LONDON.

New Process at Broken Hill. — Gold Mining in Wales. — Lancefield and its Difficulties.

Considerable interest has been evoked by the receipt of information in London relating to a new development of Broken Hill metallurgy, by means of which the slime at present untreated will be made available. The proportion of the contents extracted at Broken Hill has, perhaps, been less than at any other great mining centre. Owing to the extremely intimate mixture of the blende and galena and the presence of a heavy gangue, ore dressing has always been difficult. At first it was supposed that some smelting or leaching process might be applicable, but though many were tried the extraction was poor and the cost high. For many years operations were confined to jigging out a silver-lead concentrate, which, in most cases, was sufficient to provide profits. But this process did not recover more than a third of the metallic content of the ore. The zinc middling, as it used to be called—or zinc tailing, to give it the modern name—was useless, as was also the slime formed in the original crushing operation. The zinc tailing is now handled successfully by the various flotation processes, and according to the news at hand this week, there is a prospect of slime being utilized. Some mines produce more slime than others, but probably the average slime contains one-third of the whole value of the ore and its entry into commercial metallurgy is obviously of importance. The new process has been invented and developed by E. J. Horwood, manager of the dressing department at Broken Hill Proprietary. It consists of first separating the zinc and galena from the gangue by the flotation process and then giving the concentrate a roast at a dull red heat, which is sufficient to sulphatize or oxidize the galena, but not to affect the blende. The mixture is thus made amenable to the flotation process by which the zinc will be floated off and the lead left behind. The roasting will have to be done with exceptional accuracy, for the temperature must be kept within narrow range. The process will be applicable to many of the Tasmanian ores. Its use is not confined to slime. If coarser concentrate be treated it will not be necessary to completely sulphatize or oxidize the galena, but only to give a sufficient roast to provide a coating of sulphate or oxide. This would be sufficient to prevent the oil having any effect on the lead. I should like to see it tried on some of the complex Georgetown ores.

We occasionally hear of gold mining in Wales, and though various mines are worked energetically from time to time, the deposits are generally of too low grade, and produce disappointing results. The St. David's, near Dolgelly, is a recent example. For a few years the extraction was satisfactory and large sums were spent on new plant and development along the best lines, and as approved by mining engineers of the front rank. The mine is now, however, in a bad way. Perhaps one of the most interesting endeavors to conduct gold mining operations in Wales is that which is now under way at the Ogofan mines, in Carmarthenshire, not very far north of Swansea. These workings are so ancient that records are lost, and it is supposed that they were worked in the days of the Romans. The district is a favorite one with antiquaries, for there are Roman camps, aqueducts, and similar remains. The workings are in the form of quarries 80 or 100 ft. deep, and the sides being now covered with trees and other vegetation, the cliff scenery is quite a feature of the landscape. By computation it is reckoned that quite 4,000,000 tons were taken out in ancient days, and probably it was all oxidized ore. At various points auriferous pyritic and arsenical quartz veins are found, and it is on these that the present owners have started driving and sinking. The gold content varies, but averages 11 dwt. The results of the work are awaited with interest. A 5-stamp battery and a Wilfley table have been erected.

The Lancefield gold mine, at Laverton, Western Australia, has presented a number of metallurgical difficulties during its short history, but these appear to have been overcome, and the mine should now settle down to profitable production and become one of Bewick, Moreing & Co.'s best. The

company was first formed in 1904, and re-constructed in 1908. The ore first found was free-milling, but this changed rapidly, the ore becoming complex and presenting serious metallurgical difficulty. Arsenic came into the pyrite and the ore was hard. Dry crushing and roasting was adopted, but the presence of the arsenic and the hardness of the rock caused the output of the plant to be much less than anticipated, and the cost of treatment became correspondingly high; so high as to wipe out the margin of profit. The alternative was to increase the plant, and for this purpose additional capital was required. When the company was re-constructed in March, 1908, £30,000 working capital was obtained. Subsequently 100,000 preference shares of 10s. each were created, thus bringing up the nominal capital of the company to £200,000. The report now issued covers the period from April 1908, when the company was re-constructed, to June 30 of this year. Operations, both on the surface and underground, were suspended in July, 1908, and attention was concentrated on the treatment plant. After a thorough examination of the problem by W. J. Loring the building of six roasting furnaces was commenced in December, and in April, 1909, three were started. A fourth was brought into operation in July of this year, and the remaining two have since been completed. When the equipment is completed the monthly capacity will be 10,000 tons. Underground development was re-started in January of this year, and has since that time been continuously and actively pursued. From that date to June 30, 72,065 tons of ore have been developed, bringing the reserve to 165,234 tons containing an average of 34s. per ton, and the main shaft has been sunk to a depth of 665 ft. During the period under review, the extraction plant was working part of the time, and treated 28,389 tons with a recovery of 9537 oz., which was increased to 9848 oz. by the treatment of slag. The income from this source was £41,880, which was not sufficient by £15,390 to pay for current expenses, and did not include depreciation, development, or cost of new plant. The efficiency of the plant has increased during the last few months. In July the extraction was 80%, and by October it had increased to 86%, leaving 4s. 9d. in the residue. It is expected that eventually not more than 4s. will be left unextracted. If we take the average content at 34s. this will mean an extraction of 29s. The engineers are expecting to bring the costs down to 23 shillings.

BUTTE, MONTANA.

Tuolumne Controversy with North Butte. — Butte-Ballaklava. — Gold and Silver Output

Edward Hickey, president of the Tuolumne Copper Co., has issued a statement to stockholders relative to the controversy with the North Butte company over the rich vein on which the Tuolumne company is mining, and which the North Butte claims to be the Jessie vein of the North Butte company and belonging to the latter. To determine the rights of each the two companies are engaged in making extensive developments and surveys in the disputed ground. Since this work has been going on the Tuolumne engineers have evolved the theory that the Tuolumne and Jessie veins are separate and distinct until they reach a depth of 1200 ft., where the Jessie unites with the Tuolumne and the two form one vein, the Tuolumne claim being the older location thereby becoming the owner of the united vein from the point of junction. This is a new theory and an interesting one for North Butte owners. In his statement Mr. Hickey calls attention to the fact that the Tuolumne, consisting of six acres of surface ground, is entirely surrounded by North Butte and Amalgamated mines, and that it would therefore "be immensely desirable to them if one or the other could acquire the Tuolumne mine." Mr. Hickey says that two good veins apexing in the Tuolumne ground have been developed by the company, and one of them is the richest ever discovered in the Butte district, while a third, the largest of the number, has been cross-cut at a depth of 1800 ft. by some other company from an adjoining property. An interesting phase of the controversy lies in the fact that information from North Butte sources is that the Tuolumne and North Butte workings have come together on the 1400-

ft. level of the Tuolumne, showing that they are both on the same vein and the same orebody. Tuolumne officers say this is not true. The control of Tuolumne rests with about four or five stockholders and control of their stock could not be had at other than a satisfactory price, and not unless the same price paid them for their stock should be offered to every stockholder of the Tuolumne company for his stock. The statement of Mr. Hickey caused quite a sensation, and it was regarded that the important and significant feature was in the practical admission of an existing controversy with the North Butte and the possibility of litigation over the Tuolumne's big vein.

The Butte-Ballaklava Copper Co. will have its shaft completed to the surface by the first of the year, when a new hoist will be installed and the production increased. From the surface to the 500-ft. level the shaft was only of two compartments, while three compartments were made from the 500 down to the 1400. The additional compartment is being raised from the 500 to the surface. While that work

Montana.

has been going on mining was confined to the 100 and 300-ft. levels, from which some high-grade ore has been shipped, yielding about 7% copper and 50 oz. silver per ton.

According to the deposits made at the United States Assay Office at Helena during the first 11 months of 1909, and estimated for December, Montana produced this year \$1,517,387 in gold and silver, the different counties of the State contributing as follows:

| County. | Total value. |
|-------------------------|--------------|
| Beaverhead | \$ 739.20 |
| Broadwater | 17,133.09 |

The amount received at the Assay Office in 1908 was \$1,575,682, and in 1907 it was \$1,517,387. Practically no silver was shipped to the Assay Office from Butte, this year's total amounting to only \$64.70. Nearly all the gold and silver produced in Butte are by-products from copper, and are not extracted here, going to the refineries in the East, and they are therefore not reported to the United States Assay Office in Montana.

General Mining News.

ALASKA.

(Special Correspondence).—The operations of the Porcupine Gold Mining Co., on Porcupine creek, 40 miles from Haines, for 1909, resulted in putting the flumes and equipment in excellent condition and making a satisfactory run. The bedrock flume, 1987 ft. long, 6 ft. wide, and 4 ft. high, was finished in September. It was paved with riffle blocks the full length. The Lidgerwood trolley lift, having 2½-yd. steel buckets, with automatic dump, was put in operation late in the season. By this system the gravel is piped into the buckets at bedrock and lifted to the hopper that discharges into the sluice, at the rate of 400 cu. yd. per 20 hours. The main flume that supplies water for the giants and sluice boxes, is in perfect condition. Everything is ready for a full season's work next year, when it is estimated that 1200 to 1400 cu. yd. of gravel per day can be handled. The company expects to resume operations about May 10. E. E. Harvey, manager for the last three years, has resigned.

Seattle, December 18.

ARIZONA.

COCHISE COUNTY.

The Pawnee Mining Co., operating the Claire group, 18 miles west of Paradise, is shipping lead-silver-copper ore to the El Paso smelter.—Operations are to be resumed at the property of the Bonanza Belt Copper Co., at Johnson, after an idleness of two years.

GILA COUNTY.

(Special Correspondence).—It is expected that two of the new Nordberg pumps being installed in the 1200-ft. station of the Old Dominion mine, will be working by January 1. These have a capacity of 2,000,000 gal. per 24 hours, and will lift all the water from the 12th level to the surface. Below the 12th level electric pumps will be employed. Underground work at the Old Dominion mine is being done for the most part between the 10th and 15th levels. On the 1500-ft. level cross-cuts are being driven to cut the ore-body at the West fault. Two furnaces and two converters are in operation at the smelter.—In the cross-cut running north from the shaft on the Arizona-Michigan property an 18-in. silver-bearing vein with an east and west strike, has been cut at a distance of 130 ft. from the shaft. Since S. W. Clawson's resignation as general manager, which took effect December 1, N. A. Nelson, the superintendent, has had full charge of the Arizona-Michigan mine.—In the Jennie shaft of the Cordova property, in the Miami district, chalcocite running about 2% copper is being opened at a depth of 98 ft. Chalcocite was first cut at a depth of 84 ft. Churn-drills, for use on the north end of the Cordova property, have been ordered. M. E. McCarthy is general manager.—One of the two Star churn-drills to be used in prospecting the Schulze group of claims, owned by Samuel Newhouse and other Utah mining men, is now sinking the first hole in what is estimated to be the centre of the Pinal schist body of the property. It is believed by the management that this body of schist will contain copper.—The shaft at the Superior & Globe property is now 645 ft. deep. It is the plan to begin cross-cutting toward the Big Johnny vein at a depth of between 650 and 675 ft. H. V. Snell, of Globe, is superintendent.

Globe, December 18.

GRAHAM COUNTY.

The Keystone drill on the Celtic claim of the Copper-mines company is cutting through a hard quartzite all of which has shown a fair percentage of copper.

MARICOPA COUNTY.

William Oaches has secured an option on the Hauxhurst group 30 miles south of Wickenburg.—A new hoist and head-frame have been installed at the Interior mine and the foundation for a compressor is being constructed. F. X. O'Brien is manager.

YAVAPAI COUNTY.

The Mudhole mine, in the Walker district, which is credited with a large production, has been completely unwatered and sinking resumed in the main working shaft.—Dyson & Taylor have taken over the Eberhart mine in the same district and have 15 men at work in the property. Some good ore has been opened and the operators will install a compressor and hoist.—The Arizona Bonanza Mining Co. has purchased a boiler and 40-hp. hoist, and will install the machinery at the property in the Big Bug district. J. H. Farrel is manager.—The drift at the Mount Tritle mine, in the Hassayampa district, is in 650 ft., the face being in a fair grade of sulphide ore.

YUMA COUNTY.

A station is being cut in the adit of the Bowyer Gold & Copper Co., in the Dome Rock range, and a 25-hp. hoist will be installed.

CALIFORNIA.

NEVADA COUNTY.

The company operating the Alaska mine, at Pike City, has decided to continue operations and will sink the shaft several hundred feet deeper.

PLUMAS COUNTY.

The Plumas-Eureka mine, near Johnsville, which the Turner brothers have been operating under lease the past season, has been shut down for the winter on account of the stormy weather. The operators have opened a rich shoot of ore and milled a portion of it in the Plumas-Eureka mill, the ore being carried from the mine to mill on pack animals.—Considerable development work is being done at the Del Monte mine which was bonded to Nevada operators some time ago.

SANTA CLARA COUNTY.

A new shaft known as the Nones shaft on the property of the Quicksilver Mining Co., at New Almaden, is down 80 ft. on the vein in which the New Guadalupe Mining Co. opened a body of rich quicksilver ore.

SHASTA COUNTY.

(Special Correspondence).—W. L. Cole, superintendent of the Mountain Copper Co., Ltd., has been transferred from Martinez to Keswick to take charge of operations at the

latter point. This is taken to indicate that activities are to be resumed at Keswick if the smoke question is settled satisfactorily; plans for a new smelter are said to be ready. Development at the Hornet and Iron Mountain mines continues steadily, the new adit at the latter having opened a large amount of virgin territory. It is estimated that the production of the company for this year will be about 2,000,000 lb. of copper.—The electric iron smelter at Heroult commenced active operation December 20, producing from 15 to 20 tons of pig-iron per day. Graphite electrodes have been installed in place of the ones formerly constructed of carbon.—The Midas mine is producing at the rate of \$30,000 per month. The shaft is down 1400 ft., and over 100 men are employed.—The Gladstone is keeping 35 stamps dropping and producing approximately \$35,-

000 per month.—At the Milkmaid the new owners are preparing for work on a larger scale.—A dispatch from Boston confirms the report that the Guggenheim interests have secured a controlling option on the stock of the First National Copper Co., the holding corporation of the Balaklala. The smelter at Coram is producing at the rate of 1,500,000 lb. of blister copper per month. Two furnaces are in operation. About 700 men are employed at the mine and plant. Nothing has yet been done in regard to the construction of devices to overcome the escape of fume.—The Golinsky copper property is now in undisputed possession of Bernhard Golinsky, following a decision by the District Court of Appeals at Sacramento.—The Washington is being worked in a small way.—The Mammoth Copper Co. is actively developing the Rattlesnake silicious gold property.—The Bully Hill Copper Co. is reported to be producing at the rate of 1,000,000 lb. of copper per month.

Redding, December 21.

SUTTER COUNTY.

The Feather River Dredging & Concentrating Co. has been organized to dredge 24 miles along the channel of the Feather river above Yuba City. The company proposes to operate suction dredges reclaiming agricultural land and making the river navigable while obtaining the gold from the river bed.

TRINITY COUNTY.

The creditors of the Trinity Bonanza King Mining Co. filed a petition in the United States District Court, December 11, asking that it be adjudged bankrupt as its directors at a regular meeting, November 30, admitted the company's inability to pay its debts and its willingness to be adjudged bankrupt. The petitioning creditors are California Safe Deposit & Trust Co., by its receiver, E. J. Le Breton, \$9484, with interest since December 21, 1908, at 6%; Trinity County Water & Power Co., five promissory notes for \$50,000 each, and two for \$25,000 each, on which there is a balance due of \$230,813; and Neustadter Brothers, for supplies furnished, \$5083.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—During the last two weeks the capacity of the Capital mill has been increased from 125 to 250 tons per day, and additional Card tables have been provided.—W. Schraga, owner of the Hebrew property on Saxon mountain, has cut 2 ft. of quartz, which assays 150 oz. silver per ton. The discovery was made in sinking a winze 300 ft. from the entrance of the adit.—John Lind has started work on the Columbine mine. The adit, in 70 ft., is being driven ahead on a small streak of galena.—C. Runkle, lessee of the Colorado Central mine, has started a stope on a body of rosin blende that is 3 ft. wide. Shipments are to be made to the custom mills.—H. C. Fuller, of Boston, stated that work would be put under way in a short time in the construction of a 50-ton mill for the handling of the ore from the Centennial mine on Leavenworth mountain. D. Kennedy is manager.—Work was resumed this week on the Ramsdell mine on Lincoln mountain. The cross-cut is to be driven to intersect the Golden Jack vein. G. W. Teagarden is manager.

Georgetown, December 17.

(Special Correspondence).—A streak of ore 16 in. wide has been found in the drift at the Princess Alice mine on Fall river. The ore assays \$35 per ton gold and silver. J. F. Kaminky is manager.—A carload shipment of ore from the White mine on Red Elephant mountain was made last week that was settled for at 195 oz. silver per ton. R. B. Morton is operating the property.—A 6-in. streak of ruby silver has been uncovered on the Almaden mine. Assays of picked samples are 7710 oz. silver and 1.52 oz. gold, with 17% copper. A. Nelson is operating under lease.—Work has been resumed on the Cascade property, a former good producer.—During the month of November the Newhouse tunnel was driven 271 ft., making the total length 20,750 ft.—The working force at the Saratoga mine has been added to during the last few days and a heavy tonnage of ore is being broken. The product is to

be shipped to the Golden smelter as soon as the furnaces have been fired. John Owen is manager.—A heavy tonnage of ore is being mined in the Old Town mine, work being carried on through the Newhouse tunnel.

Idaho Springs, December 18.

GILPIN COUNTY.

(Special Correspondence).—A merger of a number of mines on Quartz hill was effected last week when the Phoenix-Burroughs group of claims was transferred to J. C. Jenkins and J. E. Lightbourn, as trustees. It is stated that a strong company is being formed and that a big campaign of development will shortly be put under way. The properties have produced \$5,000,000.—Gardi & Co., leasing on the Hall mine in Russell gulch, sent out a carload shipment of smelting ore last week that milled \$43 per ton gold and silver.—On an average three cars per week of smelting ore is being shipped by Ress & Co., leasing on the Iron mine. The product is worth from \$40 to \$45 per ton.—Outside people have secured a bond and lease on the Hughes mine situated on Bellevue mountain. Work is to be put under way in two weeks.—On the 400-ft. level of the Eureka mine a streak of free-gold ore has been uncovered

Old Town Mine.

that is 6 in. wide. Alongside of this is to be found 3 ft. of milling ore that is worth from \$18 to \$20 per ton.—The Skelton Milling & Reduction Co. has been incorporated to construct a mill that is to cost \$50,000. Custom ore will be treated.

Central City, December 16.

SAN JUAN COUNTY.

High-grade ore has been opened recently in the Detroit & Colorado mine, in the Silverton district. J. C. Bell is manager.—Suit has been brought by a number of Philadelphia stockholders against the Astor Gold Mining Co., operating near Silverton, to prevent those in control from transferring the company's property to the Gold Mining Co.—The adit being driven to tap the ore on the mill level at the Hamlet mine is in between 1500 and 1600 ft. This will open the vein over 500 ft. below the present workings from which a large amount of ore has been mined.—The experimental mill erected at the Intersection property, in Maggie gulch, has been running since the first of the month, and producing a good grade of concentrate.

SUMMIT COUNTY.

Electric drills are to be installed at the O'Reilly group, on the upper Blue river.—The roads from the Sallie Barber mine are in good condition and one carload of ore per day is being shipped.—The Country Boy mine has been closed down temporarily.—Dean & Sprague, leasing on Nigger hill, have made their third shipment of 20 tons of lead-silver-gold ore from the property.—Lessees are sinking a new shaft on the old mill-site at the Wellington mine and have opened carbonate ore at a depth of 50 ft. Two shifts are at work driving the adit that will connect with the old workings on the mill level.—Operations are being carried forward as fast as possible at the new smelter at Robinson though stormy weather has somewhat interfered with the work.

TELLER COUNTY.

Two new prospecting permits have been granted by the Gold Dollar company on its property on Beacon hill. The company is now mining about 50 tons per day.—E. J. Boughton has taken a lease on the property of the Ben Hur Mining & Milling Co., paying a flat rate of 20% of the output.—The Mary McKinney Mining Co. paid a dividend of 1c. per share on December 23.—John Sharp, operating a lease on the Abe Lincoln mine, shipped a carload of smelting ore from the 840-ft. level.—The Union Leasing Co. has opened a 3-ft. vein on the north end of the Proper claim that assays from \$15 to \$20 per ton. A shaft is down 45 ft. on the vein.—The Jerry Johnson Mining Co. paid a dividend of 1c. per share, amounting to \$25,000. A report made to the stockholders states that there is \$38,000 in the treasury and \$3000 worth of ore in transit.

IDAHO.

BONNER COUNTY.

A meeting of the stockholders of the Idaho Smelting & Refining Co. has been called for January 3, and J. Herbert Anderson, the president of the company, has announced that \$500,000 has been raised to operate the plant at Ponderay.

SHOSHONE COUNTY.

(Special Correspondence).—The Marsh Mining Co., controlled by Charles T. Cowell, B. F. Plummer, and associates, of Montana, has purchased the Cooney group of seven claims adjoining the Tiger-Poorman mine, at Burke, for \$150,000, one-fourth of which was paid in cash. A. A. Booth, of Spokane, has been appointed manager, and operations have commenced. Arrangements have been made to obtain electric power from the Hecla company, an air-compressor has been installed and work has begun with air-drills. The property is opened by adit No. 1, driven 250 ft. on the vein, and adit No. 2 cross-cutting the country rock 700 ft. and driven 130 ft. on the vein, 3 ft. of which is a lead-silver ore of shipping grade.—The United Lead Mining Co. has 20 mining claims near Osborn, in the Coeur d'Alene district, on which there is a system of veins of lead-silver ore. Two cross-cuts, driven by former owners, opened some of these veins. The lowest cross-cut is in 1700 ft., and on this a contract has been let for 1000 ft. of additional driving to cut other veins. E. W. Conrad, of Spokane, is manager for the company.

Wallace, December 18.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—A new company, the Doherty, Devitt & Sapp, has been recently organized to prospect a 160-acre tract south of Galena along Shoal creek and a contract let for 1000 ft. of drilling.—Four drills are now at work on the Taylor-Foster land recently purchased for \$12,000. After the land is thoroughly prospected the tract will be sub-leased.—A steam pump has been installed at the Monte Cristo by John Fitzgerald, and the old mine will be unwatered.—Schmidt brothers, who have been busy developing a prospect in Cave Springs, adjoining the Herald mine, have now reached the stage where a mill is necessitated. The old Equitable 200-ton mill has been bought by the company and will be removed to the new lease.—Galena now has an open-cut mine, the Newton, the only one in camp. This property showed ore at only 12 ft. below the surface, and the upper barren stratum was stripped off and the ore taken out directly from above. A 45-ft. vein is disclosed. The ore runs only 3%, but is soft and easily milled.

Galena, December 17.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The past fortnight has witnessed the transference of a number of important mining properties in this district. The 8-acre lease of the Excelsior Mining Co., at Four Corners, was bought by William Babson for a consideration of \$20,000. Recent drill-holes put down have disclosed a much better run of ore than hitherto and the drifts driven have opened a good face of ore

from 70 to 100 ft.—A 40-acre lease on the Staples land has been taken over by H. L. Kramer who has started drilling. A fair run of ore has been worked in one corner of the lease, and efforts will be made to prospect further. Mr. Kramer is already heavily interested in the Badger camp, where a large plant is in steady operation, and a number of innovations in milling practice are meeting with success.—William Goyer, of Chicago, bought a 40-acre tract of the Luke & Ash land west of Joplin upon which is situated the Sampson mine and mill for \$30,000. Mr. Goyer has held the land under lease the past year. Luke & Ash still own a 200-acre tract adjoining this land.—The Nowatt Mining Co. has bought a 50-acre tract of the Gray land for a consideration of \$15,000. This company has been drilling the property for some time and in 11 holes have struck ore from 85 to 100 ft., and a second run at 164 ft. The cuttings run from 8 to 10%. The company will begin the erection of a 300-ton mill at once and continue to prospect the remainder of the land.—Frank Nicholson has taken over a 20-acre lease on the Rex land, and has already made several turn-ins. Operations are conducted at 106 ft. in soft ground which requires timbering. Mr. Nicholson already owns the Missouri Mule at Webb City, the Hyde Park, at Porto Rico, and the Katherine at Zincite, in addition to the new property.—A lease of 10 acres on the Robb land, southwest of Joplin, has been sold to S. S. Bissell, of St. Louis, for \$20,000. The lease is well prospected, a mill has been erected on the property.—A 400-ton mill is to be erected on the Gallagher lease in the disseminated ground of West Joplin. The land has been tested by 14 drill-holes, which fully warrant shaft-sinking.

Joplin, December 16.

MONTANA.

DEER LODGE COUNTY.

The Allen company has operated a hydraulic elevator and two giants in placer mining at French Gulch, 21 miles south of Anaconda, the past season. Their ground runs from 7 to 20c. per cubic yard.

GRANITE COUNTY.

The Gold Reef Mining & Milling Co., managed by Oliver B. Finn, has just completed a cyanide plant as an addition to the stamp-mill on its property, situated eight miles from Philipsburg.

MADISON COUNTY.

A vein of tungsten ore from 12 to 18 in. wide has been cut on the property of Henry Schmidt near Twin Bridges. The value of ore so far opened approximates \$365 per ton.

NEVADA.

ELKO COUNTY.

The roads near Midas are in bad condition on account of the rainy weather so the work of hauling in the machinery for the mill of the Rex Mines company has been greatly delayed.—The Gold Circle Crown Mining Co. is to drive an adit to connect with the shaft sunk by the Snowstorm Leasing Co. Considerable work has been done on the property and three shoots opened.—At the Elko Prince a drift is being run on a 2-ft. vein that assays \$18 per ton.—A pump and hoist have been ordered for the Glasgow & Western and a shaft will be sunk on the Eastern Star claim.

ESMERALDA COUNTY.

Operations have been resumed in the Combination Fraction. On the 500-ft. level two drills are running, driving and cross-cutting, and the shaft is being sunk from the 600-ft. point.—A. C. Elslen and associates have secured a 25-year lease on the Mayflower Consolidated property and formed a new company, the stock of which is assessable.—The size of the transformer house at the Florence mine has been doubled and three new transformers added.—At the Polverde claim the shaft of the Goldfield Annex is down 700 ft., and is now in the latite.—The shaft on the Goldfield Mining & Ore Reduction Co. property is being unwatered and operations will be resumed on the 425-ft. level. The vein at this point is 6 ft. wide, and assays from \$5 to \$7 per ton.

HUMBOLDT COUNTY.

(Special Correspondence).—A reserve of ore valued at \$40,000 has been opened by the adit, raise, and winze at the Signal Peak-Consolidated properties. The orebody is said to be about 2 ft. wide, with assays averaging \$20 per ton. If sufficient water-power can be developed it is probable that a small mill will be erected in the spring. John Cleghorn is manager.—Mazuma Mines lease, on Mazuma hill, is shipping small quantities of high-grade ore. The 50-ft. winze from the 300-ft. level has intersected an 18-in. shoot of milling ore. The shaft is going down at the rate of 1 ft. per shift.—A 2-ft. vein of rich silver ore has been opened in the new shaft of the Good News. About 8 in. of the ore is said to assay \$500 per ton in horn and ruby silver. H. C. Reich is manager.—The Durango Girl is shipping small quantities of rich ore.—A number of properties in the Seven Troughs district are active.—It is reported that Eastern capitalists have become interested in the National Consolidated, the Stall brothers' claims, and other properties at National.

Rosebud, December 17.

NYE COUNTY.

(Special Correspondence).—Diamond-drilling from the 1500-ft. level of the Mizpah shaft of Tonopah of Nevada has commenced. It is reported that the shaft will be sunk to the 2000-ft. point. Owing to interference with slime settlement by the unusually cold weather, only 88 stamps were in operation last week. More heating pipes are being installed to overcome this difficulty. The mill is making an average extraction of 90%.—The Clifford properties at Ellendale continue to make small shipments of rich ore to the Hazen sampler.—A promising body of ore has been opened on the 480-ft. level at the Liberty. T. S. Carrahan, the manager, is authority for the statement that sufficient ore is blocked out to warrant the installation of 10 stamps.—The Williams, Beatty, and other lessees on Denver estate of Tramp Consolidated, are shipping steadily.—The Covert lease, on National Bank, recently made a small shipment of high-grade ore.—Driving under the vein on the 300-ft. level of the Pioneer is well under way. A strong body of quartz has been cut at the 330-ft. level, but assays are lower than in the upper workings.—It has been decided to sink the 120-ft. shaft at Bullfrog Mohawk to the 200-ft. point, and cross-cut for the main orebody. Considerable water has been found in the new workings.—The Marvel mine, near Lida, reports the uncovering of ore assaying 30% copper.—At the Cincinnati, in the same district, a 50-ft. shaft and 200-ft. adit has opened several seams of ore containing gold and copper. The shaft will be sunk to the 200-ft. level at once. Cross-cuts will be run every 50 feet.

Tonopah, December 17.

WHITE PINE COUNTY.

(Special Correspondence).—W. N. Bowen announces that operations will be resumed shortly at the Bowen-Ely group. Several shoots of gold-bearing quartz have been exposed.—The Boston-Ely shaft cut a body of copper ore at the 1060-ft. point and has penetrated it for 7 ft. without breaking through. It is said that assays of the ore show an average of 11% copper. Some gold and silver occurs.—Parties said to represent the Cole-Ryan interests have taken over the Bingham-Ely group. The Cape Box vein is the principal known orebody.—Two drills are operating steadily at Ely Central and the Eureka and Clipper shafts are going down steadily. A new shaft will be sunk on the Rex claim when the Eureka has attained sufficient depth to require a new hoist. The old plant will be then moved to the new Rex workings.—The management of the Nevada Consolidated company believes it will be able to produce copper in 1910 at a cost considerably below 7c. per lb. It is expected to produce over 70,000,000 lb. of copper in that time. It will install heavier locomotives at Copper Flat, as the ones now in use are hardly of sufficient power to satisfactorily handle the ore, as further depth is attained. Arrangements have been made with Ely Central whereby tracks may be laid on the latter property, and it is ex-

pected to have the final reverberatory furnace in operation early in 1910.

Ely, December 16.

NEW MEXICO.

SIERRA COUNTY.

(Special Correspondence).—The Silver Monument adit is in now over 1500 ft. and is expected to cut the Silver Monument vein within a short distance.—John McConaghy and H. J. Sisty have secured a number of claims on Poverty creek, and commenced active development.—The adit at the U. S. Treasury property has been completed and a raise will be made to the White Eagle shaft. When finished this will block out approximately 25,000 tons of ore in an orebody that is over 35 ft. wide.—The Vanderbilt Mining & Milling Co. has been organized to open the Vanderbilt group of claims west of Chloride. A small amount of work has been done on the property opening bornite containing some gold and silver. W. M. Armour is manager.—The California Mining & Development Co. has been organized to work a group in the southern portion of the district. Julius Wilde is manager.—At the Keystone claim, which B. L. Morrison is operating under lease, new machinery is being installed and a mill will be erected later if the ore proves satisfactory.

Chloride, December 17.

OREGON.

BAKER COUNTY.

The Commercial Mining Co., operating the Rainbow mine, between Huntington and Baker City, has paid two ½c. dividends recently, amounting to \$17,500. A sampling across 10 ft. of the vein gave an average of \$36 per ton, the actual mill-runs for November were, 258 tons, \$16.68 per ton; 236 tons, \$30.94; 236 tons, \$15.82, and 300 tons, \$22.33. The stope width is between 13 and 14 ft., and the tailing ran \$4.31 per ton.

TEXAS.

EL PASO COUNTY.

(Special Correspondence).—The International Smelting & Refining Co., of Boston, is said to be negotiating for the purchase of a site for a large smelter which it will erect near El Paso. This smelter will obtain its ores from Arizona, New Mexico, and Mexico, with the addition of what it may receive from the Texas territory adjacent to El Paso. It is reported that the proposed new smelter will be operated on a copper basis.—The American Smelting & Refining Co. will make extensive improvements to its smelter at El Paso. The decrease in the supply of lead ores is said to have caused the company to decide to make the plant available for handling additional copper ores. Roasting and calcining ovens will be installed and a converter plant erected.

El Paso, December 17.

UTAH.

JUAB COUNTY.

During the month of December the mines of the Tintic district will distribute \$225,000 to shareholders.—In the Iron Blossom mine development is being carried forward at four points in the southern portion of the mine. On the 1300-ft. level a cross-cut is being run to the ore, and on the 500 and 600-ft. levels both driving and cross-cutting is being carried forward.—The adit at the Iron King mine, in the eastern part of the district, is in over 2000 ft., and is expected to open the orebody within the next few hundred feet.—Shipments are being made regularly from the Mammoth mine, and it is the intention of the management to increase the working force at the mine the first of the year, and commence shipping on a larger scale. Samuel McIntyre is manager.—At the Arum property in North Tintic an adit is being driven to cut the vein of lead ore opened by the shaft.—The drift on the 1600-ft. level of the Chief Consolidated has entered the shoot recently opened on the 1400-ft. level, and will be continued to prospect the ground acquired by the Consolidation with the Eureka City Mining Co.—The output of the Scranton mine approximates 550 tons per month, but the management is making

arrangements to increase this by shipping some of the lower-grade ore to paint manufacturers in the East.

SALT LAKE COUNTY.

A drift has been driven 120 ft. on the ore recently cut in North Utah Mining Co.'s mine, in the Tough Nut district, and assays taken from the face run 19% lead.—The Bingham Mines and the Bingham Central Standard Mining companies have consolidated, and will build a hydro-electric plant to furnish power to develop the properties.—The Elvina vein of the Ohio Copper Co. has been recently opened on the 500-ft. level showing the ore to have a copper content of 4% with \$1.80 gold. The vein on this level is 4½ ft. wide.

WASHINGTON.

KING COUNTY.

(Special Correspondence).—The United States Government has established a rescue station at the School of Mines of the University of Washington, Seattle, for instructing and training miners in the use of the Draeger oxygen apparatus in mine rescue work. This includes instruction on the subject of mine gases. The work at this station is in charge of Hugh M. Wolfelin, of the Government Service, and D. C. Botting, State Inspector of Coal Mines. Milnor Roberts, dean of the School of Mines, has arranged for special instruction for mining classes by others outside of the regular members of the university staff, among whom are H. L. Glenn, assayer; R. S. Taylor, smelter superintendent; George J. Jamme, mining engineer, and Henry Landes, State Geologist. Many of the buildings of the Alaska-Yukon-Pacific exposition have become University property.

Seattle, December 18.

OKANOGAN COUNTY.

The Multnomah Mining & Development Co., having 600 acres of mineral land near Nespelem, has eight men at work developing. F. O. Hudnutt, formerly of Colorado, is manager. He states that a well defined vein has been opened by a 300-ft. cross-cut, the ore averaging \$7 per ton in gold, silver, and copper.

SNOHOMISH COUNTY.

The Del Campo Metals Co., of Everett, has just had an examination made of the Del Campo property which it has recently acquired. The ore is a copper-sulphide with some arsenic. There is an excellent site for a hydro-electric plant on the property should the company decide to develop its own power.

STEVENS COUNTY.

(Special Correspondence).—Frank Davy, lessee of the Old Bonanza mine, four miles east of Bossburg, is opening large bodies of silver-lead ore under the old workings and getting profitable returns from the smelter.—A rich deposit of copper ore has been found at a depth of 280 ft. in the Little Giant mine, three miles east of Rockcut. About \$25,000 has been spent by the company on the property.—The most important find in the First Thought mine has been made on the 480-ft. level. Samples from a diamond-drill hole assayed from \$3000 to \$4000 in gold per ton.—The Iago company is preparing to sink a deep shaft on its property near Orient. It will follow the vein from which a number of good assays have been obtained.—Ore has been cut by the adit of the Valley Dew mine.—The Spencer Consolidated Mines Co. has resumed work on its property in the Fisher camp, eight miles east of Orient, after a period of five years of idleness.—In the Tungsten King mine, near Deer Park, ore was found recently which assayed 62% tin. The framework for the concentrator has been set up, and the machinery is now being installed.—At Metaline all of the property of the Spokane Lead Mines has been taken over by an Eastern syndicate which will pay off the indebtedness against the company and start working immediately.—Samples of ore brought from the M. T. mine, in the northern part of the county, assayed as high as \$191 gold and 18 oz. silver per ton. The company is reported to be making a trial shipment of a carload of ore.

Colville, December 18.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The Consolidated Mining & Smelting Co., of Canada, has purchased the Ikeda group of claims from its Japanese owners. This property, comprising 26 copper claims around Ikeda bay, Moresby island, of the Queen Charlotte group, is practically the only group in that district on which any important amount of development has been done. Two-thirds of the ore shipped from the mine is second class and assays 6% copper, \$4 gold, and \$2 silver; this is run of mine. The first-class ore assays 14% copper, \$6 gold, and \$2.50 silver. The claims were found by Japanese fishermen several years ago, and have been considerably developed on the Lilly group by Awaya, Ikeda & Co., of Vancouver. The property is equipped with an engine, compressor, and 1000-ton ore bunkers at the wharf.—The big stope in the War Eagle ground of the Consolidated is yielding a heavy tonnage of good ore, and, if anything, improving as work goes on. A new stope was opened on the fourth level of the Idaho claim during the week.—At the Velvet-Portland the lessee is working on the third and fourth levels and loading a couple of cars per week, hauling the ore over good snow roads.—As was anticipated, the Granby Consolidated, at its recent meeting of the directors, declared a dividend of 2%, which, on the 135,000 \$100 shares outstanding, will amount in all to \$270,000. This is the eleventh dividend paid by the Granby company since December, 1903; the amount of money shared with the stockholders since that time amounting to \$3,778,630. Dividends amounting to 9% were paid in 1907 and 4% in 1908. The decrease to 2% this year is attributed to the cost of recent improvements of smelting and converting plant. With an improvement in the copper market there is no reason why this company should not pay 10% during 1910, as the mines and smelter are in better form than they have ever been.—The Consolidated Mining & Smelting Co. has bought a mill-site at Boundary Falls, and will erect a concentrator there in the near future to treat the ore from its recently acquired No. 7 mine, near the Central camp.—Four new properties made initial shipments to the Trail smelter during the week, these being the Golden Cup, Meteor, Ohio, and Payday.—The final payment by the Amalgamated Gold Mines of Sheep Creek, Ltd., on a bond covering 25 claims in the heart of the Sheep Creek district, has been made.—A plan of deep development is outlined for the Payne mine. A rich shoot of ore has been cut on the eighth level, thought to be a continuation of the old vein.—Ore has been struck at depth in the Surprise mine, at Sandon, and driving is now being done to ascertain the value of the find.—The Quesnelle Hydraulic Gold Mining Co. is building a dam at Swift river 600 ft. long and 45 ft. high, and will bring 4000 miners' inches of water 26 miles to its property on Quesnelle river. Two miles of 5-in. pipe will be bought in the spring and other additions to the plant made. The company will work 800 men next summer. H. B. Ferguson, of Vancouver, is the engineer in charge of the work.

Rossland, December 16.

The Columbia Copper Co., whose property is on Friday creek, 12 miles from Princeton, is planning the installation of a hydro-electric plant and air-compressor next spring. It is claimed the company has an extensive body of high-grade copper ore. E. P. Wheeler is manager.—M. K. Rogers made the final payment of \$135,000 on the Hidden Creek mine near Fort Simpson. A large amount has been spent in development and it is estimated that \$2,000,000 worth of ore has been blocked out.

MEXICO.

MEXICO.

The Seguranza Mining Co., which is operating the old Amp. de Olvidado claim, in the Zacualpán district, has unwatered the property and is now stopping ore. Electric motors have been installed in the new 100-ton mill and connections made from the main line to the sub-station.—Ore assaying 4 kg. silver and 30% lead has been cut by the adit of the Imperial Mining Co.—The old Rosario adit has been cleaned out by the Veta Negra company and the workings are being sampled.

Personal.

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. A. HEYWOOD is in Russia.
E. L. OLIVER is in San Francisco.
HERBERT T. BUTCHER is in Algeria.
H. KILBURN SCOTT has been in Spain.
LEWIS T. WRIGHT has gone to London.
HOWARD D. SMITH has gone to French Guinea.
W. H. TREWARTHA-JAMES has arrived in London.
WALTER McDERMOTT is on his way to Johannesburg.
ARTHUR L. PEARSE is on his way back from Alaska.
C. M. ROLKER has returned to London from California.
F. C. BRAY, recently at Abosso, West Africa, is returning to England.

HENRY E. KUPHAL, formerly in California, is now at Missoula, Montana.

C. BARING HORWOOD is manager for the Randfontein South mine at Johannesburg.

F. LYNWOOD GARRISON has left San Francisco for Philadelphia.

J. W. MERCER passed through London on his way to the Continent.

HARRY H. WEBB has returned to London from New York and California.

WALTER G. PERKINS is in London and will soon return to San Francisco.

E. GYBSON SPILSBURY has been examining mines at Tonopah, Nevada.

G. E. WEBBER is returning to Johannesburg, much improved in health.

R. B. NICKERSON has arrived in San Francisco from Rat Portage, Ontario.

R. B. LAMB, of the C. L. Constant Co., will be in northern Mexico about two weeks.

TUDOR G. TREVOR is Inspector of Mines in the Barberton district of the Transvaal.

H. A. TITCOMB is at Salt Lake City, in connection with the Silver King litigation.

F. G. A. ROBERTS, manager of the Knight's Central, Johannesburg, is visiting England.

WALTER McDERMOTT is on his way to Johannesburg, where he will remain three months.

J. W. SUTHERLAND, manager of the Golden Horseshoe mine, is in London from Kalgoorlie.

NEWTON B. KNOX is on his way to Burma to examine tin mines. He will return to London in March.

MARTIN J. HELLER is visiting the Consolidated Arizona smelter, Humboldt, Arizona, as consulting engineer.

A. S. WELLS, of Portland, Oregon, recently examined a placer mining property in the Altar district, Sonora, Mexico.

DESAIX B. MYERS will be at Culiacán, Mexico, January 1 to February 15, after which date he will return to Los Angeles.

GILBERT WALKER arrived at Cape Town in November to negotiate with the Government for the establishment of a steel industry.

P. R. WHITMAN has left the Virginia & Mexico mine, Hostotipaquillo district, to accept a position with the Real del Monte at Pachuca, Mexico.

THE SAN FRANCISCO SECTION of the Mining & Metallurgical Society of America met, following dinner, at the Palace Hotel, December 20. The members and guests present were, S. B. Christy, F. Lynwood Garrison, Clifford Dennis, F. W. Bradley, G. T. Coffee, Eugene Kennedy, E. L. Oliver, C. W. Merrill, L. D. Mills, John D. Hoffmann, Ross B. Hoffmann, C. H. Munro, George Hoffmann, M. L. Requa, J. Ross Browne, Corey C. Brayton, E. J. Molero, and H. F. Bain. The establishment and functions of a National Bureau of Mines was considered.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

EXCESSIVE LOCATION OF MINE.

An excessive mineral location made in good faith and conforming otherwise to the legal requirements is not wholly void, but invalid as to the excessive area only, and in such case, the locator may select the portion of the claim he will reject as such excess.

Waskey v. Hammer, 170 Fed. 31, May '09.

BURNING MINE NOT A NUISANCE.

A mine within the limits of a city and which was being consumed by fire that had existed for two or three years, and was beyond the control of the lessee which had expended its entire capital stock in an effort to extinguish the fire, was held not such a nuisance that the lessee could be ordered to abate. The lessee in such case could at most only be compelled to use its corporate assets and funds in an effort to put out the fire, and this having been done, a court of equity would not compel it to do any more.

McCabe v. Watt, (Pa.) 73 Atl. 453, March '09.

LOCATION OF MINE—CHANGE IN BOUNDARY.

It is immaterial whether the discovery of mineral in the ground claimed and located is made before or after the marking of its boundaries, and the performance of such acts, where recording notice of the location is not required, perfects the location. Hence the fact that a locator on discovering that his boundaries exceeded the amount of ground to which he was entitled, changed one of the lines so as to exclude such excess, and in so doing, he excluded the hole in which he made his discovery; but this did not vitiate his entire claim, provided he made another discovery within the boundaries as changed before any rights in the premises had been acquired by another.

Waskey v. Hammer, 170 Fed. 31, May '09.

PURCHASE OF MINING CLAIM—LIABILITY OF THIRD PERSON FOR FRAUD.

The lessees of a mining claim had an option to purchase the claim for \$75,000, but by a separate agreement the owner and lessor agreed in case of purchase to refund to the lessees the sum of \$35,000 of the purchase price. The lessees by false representations and by concealing the fact of the second agreement, induced a third person to become a joint purchaser with them and to pay \$37,500 for a half interest in the claim. The lessees not having sufficient money, applied to another third person, stating to him the facts and showing him both contracts, and he thereupon agreed to advance the money necessary to make the payments until the real consideration of \$40,000 should be paid, and thereupon he was to secretly receive the subsequent payments made by the purchaser taking such half interest with the lessees; and for this accommodation he was to receive also a third interest in the half of the claim that was to be conveyed to the original lessees. After the first payment of \$20,000, the purchaser of such half interest became suspicious and refused to pay more, and thereupon such other third person advancing the money for the lessees, completed the payments and obtained title to the property. Subsequently, the original purchaser of the half interest of the claim sued the person advancing the money for the lessees and who subsequently purchased the entire claim, to recover the sum originally paid by him. And the person thus advancing the money for the lessees and afterward purchasing the claim was held liable on the ground that by intentionally joining with the lessees in the deception, he thereby became a joint purchaser and assumed the obligations of good faith incident to that relation, and that both he and the property in his hands were liable for the amount necessary to make restitution for the fraud.

Cunningham v. Pettigrew, 169 Fed. 335, Jan. 09.

Publications Received.

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MINERAL PRODUCTION OF CALIFORNIA FOR 1908. California State Mining Bureau, Bull. 54, 1909. A table showing production by counties.

MINERAL PRODUCTION OF CALIFORNIA. California State Mining Bureau, Bull. 55, 1909.

The production for the past 22 years is presented in tabular form by subject.

UNIVERSITY OF PITTSBURG. School of Mines Edition. Bull. Vol. V, No. 2. Pp. 158. Pittsburg, 1909.

A general account of the organization of the school with plans for its work.

MINERAL RESOURCES OF THE UNITED STATES IN 1908. U. S. Geological Survey, Washington, 1909. Advance chapters as follows are now available: Platinum, D. T. Day; Stone and Lime, A. T. Coons; Silver, Copper, Lead, and Zinc in the Central States, B. S. Butler and C. E. Siebenthal; Tungsten, Nickel, Cobalt, Vanadium, Titanium, Molybdenum, Uranium, and Tantalum, F. L. Hess.

PHYSICAL FEATURES OF THE DES PLAINES VALLEY. By J. W. Goldthwaite. Illinois State Geol. Surv., Bull. 11. Pp. 103, ill., index. Urbana, 1909.

This forms the second of the bulletins in the 'Educational Series' which the Illinois Survey is publishing. Mr. Goldthwaite has made excellent use of the interesting material which he had and the result is a bulletin which will be of more than local interest to geologists and physiographers as well as laymen.

THE PREVENTION OF INDUSTRIAL ACCIDENTS. The Fidelity & Casualty Co., of New York. Pp. 190. New York, 1909. Price 25 cents.

This is a general, illustrated discussion of the causes and means of prevention of accidents especially in connection with steam boilers, engines, elevators, electric apparatus, and under general factory conditions. It has been carefully prepared by F. E. Law and William Newell, of the staff of the Casualty company. A similar pamphlet discussing mining conditions would be of great value.

DESCRIPTIVE SKETCH OF THE GEOLOGY AND ECONOMIC MINERALS OF CANADA. By G. A. Young, with introduction by R. W. Brock, Canada, Department of Mines, Geological Survey Branch. Pub. N. 1085, Pp. 151, ill., index, map.

The usefulness of such general handbooks as this is widely recognized. In a country such as Canada where, as Mr. Brock points out, less than half the territory has been prospected, it is peculiarly necessary to issue repeated editions of works which disseminate what little is known. Only by educating many to the possibilities of the field can its resources be developed. From 1886 to 1909 the per capita mineral production increased from \$2.23 to \$12.57, having in 1908 amounted to a total of \$87,000,000. From this it can be seen that the excellent work done by the Geological Survey and the Mines Branch is bringing results.

THE RECOGNITION OF MINERALS. By C. G. Moor. With monographs on Geology, Ore Deposits, etc., by Donald A. MacAllister. Pp. 245, index. *The Mining Journal*, London, 1909. Price \$2.25.

The avoidance of scientific method and terms in this book will commend it to those unused to technical treatises. Unfortunately the statements are sometimes misleading, for example, where it is said that quartz is an essential constituent only of acid and moderately acid rocks; and again where the affirmation is made that "all ores tend to 'slime' more or less; some, such as cinnabar and copper carbonate, so much so that wet treatment is nearly useless." The selection of these examples of sliming ores completely misses the point of difficulty which arises in practice with the ores which any metallurgist would undertake to treat. The book is wide in its scope, but is essentially amateurish.

Calorific Value of California Fuel Oil.

By R. W. FENN.

*The accompanying tabulated comparison of California crude oils of different densities has been compiled as below from a large number of laboratory and running tests made by various chemists and practical experts. The primary object in preparing this table was to ascertain definitely whether there was any absolute connection between the density, as indicated by degrees of the Baumé scale, and the calorific value of the oils. The result of a careful digestion and comparison of the data secured from diverse but reliable sources was the justification of the belief that a perfect sliding scale would quite accurately conform to practical calorific values.

It must be borne in mind, however, that for practical purposes no table can be made more than closely approximate in character, owing to the great variety of methods used in burning the oil, the efficiency of some methods being considerably greater than that of others, and owing also to the intermittent character of tests made with the same burner and equipment, due to clogging of burners, change of draft, or the personal equations of those in charge of the plant.

*Engineering News, Vol. 61, No. 19.

A Primer on Explosives.

In continuance of its efforts to reduce the number of fatal accidents in American coal mines, the United States Geological Survey has just issued a primer for the benefit of miners and others who have anything to do with explosives. The book, which is written in plain, non-technical language, describes how and of what materials explosives are made, points out the dangers in their use, and shows how these may be avoided or reduced to a minimum.

The improper use of explosives in coal mines is doubtless the cause of many deaths that are attributed to other agencies. Vigorous objection is made to the use of black powder in any mine where there is danger of a gas or coal-

dust explosion. The operators and miners in such mines are urged to use explosives that have been tested at the Survey's mine-accident station at Pittsburg, Pennsylvania, and placed on the 'permissible' list. Investigations at this station have proved that the flame from the explosion of black powder lasts from 2500 to 3500 times as long as the flame from the newer explosives, and is therefore more likely to ignite gas or dust in mines.

The use of explosives is increasing both in quantity and in the variety of purposes to which they are applied. They are now made at 150 plants in different parts of the country, and the product of a single year is now nearly 500,000,000 lb. Of all this material no explosive is safe in the hands of a careless or ignorant person, whether it is used in mining or otherwise. Statistics recently compiled by the railway bureau for the safe transportation of explosives show that more than 400 persons have been killed or injured and over \$3,000,000 worth of property destroyed by explosives in transit by rail. The fact that three years of co-operative effort under the supervision of this bureau have reduced these losses to almost nothing should encourage the hope that similar co-operative efforts may likewise greatly reduce losses of life and property from the use of explosives in mining.

The additions from time to time to the large death roll of our mines make a recurring appeal to the American public for fair treatment of the coal-mining industry and to the miner and the manager that they co-operate in every possible effort for greater safety. It may not be possible under existing conditions to prevent all mine accidents. Little may be done by either the operators or the miners working alone, but experience in all countries shows that by hearty and determined co-operation of the two these accidents may be greatly reduced. This can be accomplished only by means of wise laws and regulations based on fact and experience, and by the strictest possible discipline.

Tungsten.

A report on the tungsten ores of Canada, by T. L. Walker, of Toronto University, has recently been issued by the Mines Branch of the Department of Mines of Canada at Ottawa. The report covers 56 pages. Among the rare metals which have recently become of commercial value, tungsten is an important example. One of its newest applications is as a filament in incandescent lamps, in which it gives a much more brilliant light with greater efficiency than carbon. Its most important use, however, is in the manufacture of tungsten steel, to which it imparts great elasticity and tensile strength. The metal has, therefore, become particularly valuable to the manufacturers of special steels. The known occurrences of tungsten ores throughout the world are comparatively few, which fact lends additional interest to some discoveries of scheelite (an ore of tungsten), which have been made within the past two years in Nova Scotia. These, together with other occurrences of tungsten ores in Canada, have been made the subject of the present report, which is designed to present to those interested all the available information on these ores. The several occurrences of tungsten ore in Canada are described in detail, and a general statement is given on the geological occurrence of the ores, chemical tests, concentration, the uses of the metal, producing mines in other countries, and statistics of the world's production, while a useful bibliography of the literature on Canadian and United States occurrences is added.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to October 1909:

| | |
|------------------------|---------|
| | Tons. |
| Imports of copper..... | 130,556 |
| Exports of copper..... | 6,699 |

Consumption of copper..... 123,857
as compared with consumption during the same period in 1908 of 128,006 tons. Of the above quantity 119,329 tons was imported from the United States.
